F21SC Industrial Programming: Python Introduction & Control Flow

Hans-Wolfgang Loidl

School of Mathematical and Computer Sciences, Heriot-Watt University, Edinburgh

Semester 1 — 2021/22

⁰No proprietary software has been used in producing these slides (1) (1)

Outline

- Python Overview
- Getting started with Python
- Control structures
- Functions

Contents

- Python Overview
- Getting started with Python
- Control structures
- 4 Functions

Online Resources

- www.python.org: official website
- Course mostly based on Guido van Rossum's tutorial.
- For textbooks in Python introductions see the end of this slideset.
- Stable version: 3.8 (Oct 2019)
- Latest version: 3.10 (Oct 2021)
- Implemented in C (CPython)

Python

- Python is named after Monty Python's Flying Circus
- Python is an object-oriented language focussing on rapid prototyping
- Python is a scripting language
- Python features an elegant language design, is easy to learn and comprehend
- Open source
- Highly portable
- First version was made available 1990
- Current stable version is 3.8 (Oct 2019)

Python 3 vs Python 2

We will use Python 3, which offers several important new concepts over Python 2.

If you find Python 2 code samples, they might not run with python3. There is a tool python3-2to3 which tells you what to change (and it works in most cases). The most common issues are

- In Python 3, print is treated as any other function, especially you need to use parentheses as in write print (x) NOT print x
- Focus on iterators: pattern-like functions (e.g. map) now return iterators, i.e. a handle used to perform iteration, rather than a data structure.

For details check:

https://www.python.org/downloads/release/python-363/

Runtime behaviour

- Python source code is compiled to byte-code, which is then interpreted
- Compilation is performed transparently
- Automatic memory management using reference counting based garbage collection
- No uncontrolled crash (as in seg faults)

Language features

- Everything is an object (pure object-oriented design)
- Features classes and multiple inheritance
- Higher-order functions (similar to Scheme)
- Dynamic typing and polymorphism
- Exceptions as in Java
- Static scoping and modules
- Operator overloading
- Block structure with semantic-bearing indentation ("off-side rule" as in Haskell)

Data types

- Numbers: int, long, float, complex
- Strings (similar to Java)
- Tuples, Lists, Dictionaries
- Add-on modules can define new data-types
- Can model arbitrary data-structures using classes

Why Python?

- Code $2 10 \times$ shorter than C#, C++, Java
- Code is easy to comprehend
- Encourages rapid prototyping
- Good for web scripting
- Scientific applications (numerical computation, natural language processing, data visualisation, etc)
- Python is increasingly used at US universities as a starting language
- Rich libraries for XML, Databases, Graphics, etc.
- Web content management (Zope/Plone)
- GNU Mailman
- JPython

Python vs. other languages

- Very active community
- A lot of good libraries
- Increasingly used in teaching (MIT, Berkeley, etc)
- Good online teaching material, e.g. Online Python Tutor
- Picks up many advanced language features from other languages (e.g. Haskell)

Python Textbooks (Advanced)

- Mark Lutz, "Programming Python." O'Reilly Media; 4 edition (10 Jan 2011). ISBN-10: 0596158106. Good texbook for more experienced programmers. Detailed coverage of libraries.
- David M. Beazley, "Python Essential Reference." Addison Wesley; 4 edition (9 July 2009). ISBN-10: 0672329786. Detailed reference guide to Python and libraries.
- Alex Martelli, Anna Ravenscroft, Steve Holden, "Python in a Nutshell."
 O'Reilly Media; 3rd edition (May 2017). ISBN-13: 978-1449392925

O'Reilly Media; 3rd edition (May 2017). ISBN-13: 978-1449392925 Concise summary of Python language and libraries.

- Mark Lutz, "Learning Python.", 5th edition, O'Reilly, 2013. ISBN-10: 1449355730 Introduction to Python, assuming little programming experience.
- John Guttag. "Introduction to Computation and Programming Using Python.", MIT Press, 2013. ISBN: 9780262519632. Doesn't assume any programming background.
- Timothy Budd. "Exploring Python.", McGraw-Hill Science, 2009. ISBN: 9780073523378. Exploring Python provides an accessible and reliable introduction into programming with the Python language.

- Zed A. Shaw. "Learn Python the Hard Way.", Heavily exercise-based introduction to programming. Good on-line material.
- Michael Dawson, "Python Programming for the Absolute Beginner.",
 3rd edition, Cengage Learning PTR, 2010. ISBN-10: 1435455002 Good introduction for beginners. Slightly dated. Teaches the principles of programming through simple game creation.
- Tony Gaddis, "Starting Out with Python.",
 Pearson New International Edition, 2013. ISBN-10: 1292025913
 Good introduction for beginners..

Online resources:

- How to Think Like a Computer Scientist.
- An Introduction to Python.
- Dive into Python 3.
- Google's Python Class.
- Main Python web page.

For this course:

- Main course information page: http://www.macs.hw.ac.uk/ hwloidl/Courses/F21SC/index_new.html.
- Python sample code: http://www.macs.hw.ac.uk/ hwloidl/Courses/F21SC/Samples/python_sample
- FAQs: http://www.macs.hw.ac.uk/ hwloidl/Courses/F21SC/faq.html#python

Online resources:

- How to Think Like a Computer Scientist.
- An Introduction to Python.
- Dive into Python 3.
- Google's Python Class.
- Main Python web page.

For this course:

- Main course information page: http://www.macs.hw.ac.uk/ hwloidl/Courses/F21SC/index_new.html.
- Python sample code: http://www.macs.hw.ac.uk/ hwloidl/Courses/F21SC/Samples/python_sample
- FAQs: http://www.macs.hw.ac.uk/ hwloidl/Courses/F21SC/faq.html#python

Launching Python

- Interactive Python shell: python
- Exit with eof (Unix: Ctrl-D, Windows: Ctrl-Z)
- Or: import sys; sys.exit()
- Execute a script: python myfile.py
 python3 ..python-args.. script.py ..script-args..
- Evaluate a Python expression

```
python3 -c "print (5*6*7)"
python3 -c "import sys; print (sys.maxint)"
python3 -c "import sys; print (sys.argv)" 1 2 3 4
```

Executable Python script

```
#!/usr/bin/env python3
# -*- coding: iso-8859-15 -*-
```

Integer Arithmetic

>>> is the Python prompt, asking for input

```
>>> 2+2 # A comment on the same line as code.
4
>>> # A comment; Python asks for a continuation ..
... 2+2
>>> (50-5*6)/4
5.0
>>> # Use // for integer division (returns floor):
... 7//3
2
>>> 7//-3
-3
```

Arbitrary precision integers

• int represents signed integers (32/64 Bit).

```
>>> import sys; sys.maxint 2147483647
```

• long represents arbitrary precision integers.

```
>>> sys.maxint + 1
2147483648L
>>> 2 ** 100
1267650600228229401496703205376L
```

Conversion: ["_" is a place-holder for an absent value.]

```
>>> - 2 ** 31
-2147483648L
>>> int(_)
-2147483648
```

Assignment

Variables don't have to be declared (scripting language).

```
>>> width = 20
>>> height = 5*9
>>> width * height
900
```

Parallel assignments:

```
>>> width, height = height, width + height
```

Short-hand notation for parallel assignments:

```
>>> x = y = z = 0  # Zero x, y and z
>>> x
0
>>> z
```

Floating-point numbers

- Arithmetic operations are overloaded.
- Integers will be converted on demand:

```
>>> 3 * 3.75 / .5
22.5
>>> 7. / 2
3.5
>>> float(7) / 2
3.5
```

- Exponent notation: 1e0 1.0e+1 1e-1 .1e-2
- Typically with 53 bit precision (as double in C).

```
>>> 1e-323
9.8813129168249309e-324
>>> 1e-324
0.0
```

Further arithmetic operations

Remainder:

Division and Floor:

Complex Numbers

Imaginary numbers have the suffix j.

```
>>> 1j * complex(0,1)
(-1+0j)
>>> complex(-1,0) ** 0.5
(6.1230317691118863e-17+1j)
```

Real- and imaginary components:

```
>>> a=1.5+0.5j
>>> a.real + a.imag
2.0
```

Absolute value is also defined on complex.

```
>>> abs(3 + 4j)
5.0
```

Bit-operations

• Left- (<<) and right-shift (>>)

```
>>> 1 << 16 65536
```

Bitwise and (&), or (↑), xor (ˆ) and negation (˜).

```
>>> 1000 & 0377
232
>>> 0x7531 | 0x8ace
65535
>>> ~0
-1
>>> 0123 ^ 0123
```

Strings

- Type: str.
- Single- and double-quotes can be used

```
Input
-----
'Python tutorial' 'Python tutorial'
'doesn't' "doesn't"
"doesn't" "doesn't"
'"Yes," he said.' '"Yes," he said.'
"\"Yes,\" he said." '"Yes," he said.'
'"Isn\'t," she said.' '"Isn\'t," she said.'
```

Escape-Sequences

```
\\ backslash
\' single quote
\" double quote
\t tab
\n newline
\r carriage return
\b backspace
```

Multi-line string constants

The expression

```
print ("This is a rather long string containing\n\
several lines of text as you would do in C.\n\
    Whitespace at the beginning of the line is\
 significant.")
```

displays this text

This is a rather long string containing several lines of text as you would do in C. Whitespace at the beginning of the line is sign

Triple-quote

Multi-line string including line-breaks:

gives

```
Usage: thingy [OPTIONS]

-h Display this usage message
-H hostname Hostname to connect to
```

Raw strings

An r as prefix preserves all escape-sequences.

```
>>> print ("Hello! \n\"How are you?\"")
Hello!
"How are you?"
>>> print (r"Hello! \n\"How are you?\"")
Hello! \n\"How are you?\"
```

Raw strings also have type str.

```
>>> type ("\n")
<type 'str'>
>>> type (r"\n")
<type 'str'>
```

Unicode

• Unicode-strings (own type) start with u.

```
>>> print ("a\u0020b")
a b
>>> "\xf6"
"ö"
>>> type (_)
<type 'unicode'>
```

Standard strings are converted to unicode-strings on demand:

```
>>> "this " + "\u00f6" + " umlaut"
'this ö umlaut'
>>> print _
this ö umlaut
```

String operations

```
"hello"+"world"
                      "helloworld"
                                          # concat.
 hello**3
                      "hellohellohello"
                                         # repetition
 "hello"[0]
                      "h"
                                          # indexing
 "hello"[-1]
                      " 0 "
                                          # (from end)
                      "ell"
 "hello"[1:4]
                                            slicing
 len("hello")
                                          # size
 "hello" < "jello"
                      True
                                          # comparison
 "e" in "hello"
                                          # search
                      True
```

Lists

Lists are mutable arrays.

```
a = [99, "bottles of beer", ["on", "the", "wall"]]
```

String operations also work on lists.

```
a+b, a*3, a[0], a[-1], a[1:], len(a)
```

Elements and segments can be modified.

More list operations

```
>>> a = range(5)
                           # [0,1,2,3,4]
                           # [0,1,2,3,4,5]
>>> a.append(5)
                           # [0,1,2,3,4]
>>> a.pop()
5
>>> a.insert(0, 42)
                           # [42,0,1,2,3,4]
                           # [0,1,2,3,4]
>>> a.pop(0)
42
                           # [4,3,2,1,0]
>>> a.reverse()
                           # [0,1,2,3,4]
>>> a.sort()
```

N.B.: Use append for push.

While

Print all Fibonacci numbers up to 100 (interactive):

```
>>> a, b = 0, 1
>>> while b <= 100:
... print (b)
... a, b = b, a+b
```

- Comparison operators: == < > <= >= !=
- NB: Indentation carries semantics in Python:
 - Indentation starts a block
 - De-indentation ends a block
- Or:

```
>>> a, b = 0, 1
>>> while b <= 100: print (b); a,b = b, a+b
```

```
Example
```

```
x = int(input("Please enter an integer: "))
if x < 0:
     y = -1
     print('Sign is Minus')
elif x == 0:
     print('Sign is Zero')
elif x > 0:
     print('Sign is Plus')
else:
     print('Should never see that')
```

NB: elif instead od else if to avoid further indentations.

F20SC/F21SC — 2021/22

For

for iterates over a sequence (e.g. list, string)

```
Example
a = ['cat', 'window', 'defenestrate']
for x in a:
    print(x, len(x))
```

 NB: The iterated sequence must not be modified in the body of the loop! However, it's possible to create a copy, e.g. using segment notation.

```
for x in a[:]:
    if len(x) > 6: a.insert(0,x)
print (a)
```

Results in

['defenestrate', 'cat', 'window', 'defenestratewill

Range function

• Iteration over a sequence of numbers can be simplified using the range () function:

```
>>> range(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> range(5, 10)
[5, 6, 7, 8, 9]
>>> range(0, 10, 3)
[0, 3, 6, 9]
>>> range(-10, -100, -30)
[-10, -40, -70]
```

• Iteration over the indices of an array can be done like this:

```
a = ['Mary', 'had', 'a', 'little', 'lamb']
for i in range(len(a)):
    print (i, a[i])
```

For-/While-loops: break, continue, else

- break (as in C), terminates the enclosing loop immediately.
- continue (as in C), jumps to the next iteration of the enclosing loop.
- The else-part of a loop will only be executed, if the loop hasn't been terminated using break construct.

```
for n in range(2, 10):
    for x in range(2, n):
        if n % x == 0:
            print (n, 'equals', x, '*', n//x)
            break
    else: # loop completed, no factor
        print (n, 'is a prime number')
```

The empty expression

• The expression pass does nothing.

```
while True:
    pass # Busy-wait for keyboard interrupt
```

 This construct can be used, if an expression is syntactically required, but doesn't have to perform any work.

Procedures

Procedures are defined using the key word def.

```
def fib(n):  # write Fibonacci series up to n
   """Print a Fibonacci series up to n."""
   a, b = 0, 1
   while b < n:
      print (b)
      a, b = b, a+b</pre>
```

- Variables n, a, b are local.
- The return value is None (hence, it is a procedure rather than a function).

```
print (fib(10))
```

A procedure as an object

Procedures are values in-themselves.

```
>>> fib
<function fib at 10042ed0>
>>> f = fib
>>> f(100)
1 1 2 3 5 8 13 21 34 55 89
```

Call-by-value

- When passing arguments to functions, a Call-by-value discipline is used (as in C, C++, or C#).
- Assignment to parameters of a function are local.

```
def bla(1):
    1 = [1]
1 = ['not', 'empty']
bla(1)
print(1)
```

- 1 is a reference to an object.
- The referenced object can be modified:

```
def exclamate(1):
    1.append('!')
exclamate(1)
print(1)
```

Global Variables

The access to a global variable has to be explicitly declared.

```
def clear_l():
    global l
    l = []

l = ['not', 'empty']
clear_l()
print(l)
```

Global Variables

• The access to a global variable has to be explicitly declared.

```
def clear_l():
    global l
    l = []

l = ['not', 'empty']
clear_l()
print(l)
```

• ... prints the empty list.

Return values

- The return construct immediately terminates the procedure.
- The return ...value... construct also returns a concrete result value.

```
def fib2(n):
    """Return the Fibonacci series up to n."""
    result = []
    a, b = 0, 1
    while b < n:
        result.append(b) # see below
        a, b = b, a+b
    return result
f100 = fib2(100) # call it
f100
                    # write the result
```

Default values for function parameters

 In a function definition, default values can be specified for parameters:

```
def ask(prompt, retries=4, complaint='Yes/no?'):
  while True:
    ok = raw_input(prompt)
    if ok in ('y', 'ye', 'yes'): return True
    if ok in ('n', 'no'): return False
    ret.ries -= 1
    if retries < 0: raise IOError, 'refused'
    print (complaint)
```

When calling the function, some arguments can be omitted.

```
ask ("Continue (y/n)?", 3, "Yes or no, please!")
ask ("Continue (y/n)?", 3)
ask ("Continue (y/n)?")
```

Python Intro

Default values for function parameters (cont'd)

Wrong:

```
ask ("Continue (y/n)?", "Yes or no, please!") ask ()
```

 Named arguments (keyword arg) are useful when using arguments with and without default values:

```
ask ("Continue (y/n)?", complaint="Yes or no?") ask (prompt="Continue (y/n)?")
```

Wrong:

```
ask (prompt="Continue (y/n)?", 5)
ask ("Yes/no?", prompt="Continue (y/n)?")
```

45/76

Evaluation of default values:

 Default values will be evaluated only once, when the function is defined:

```
i = 5
def f(arg=i):
    print (arg)
i = 6
f()
```

Which number will be printed?

•

Evaluation of default values:

 Default values will be evaluated only once, when the function is defined:

```
i = 5
def f(arg=i):
    print (arg)
i = 6
f()
```

- Which number will be printed?
- ... prints 5.

Evaluation of default values

Beware of mutable objects!

```
def f(a, L=[]):
      L.append(a)
      return L
 print (f(1))
  print (f(2))
• ... prints [1] and [1, 2]. However:
  def f(a, L=None):
      if L is None:
           L = []
      L.append(a)
      return L
• ... prints [1] and [2].
```

WATT

Argument lists

 Prefixing a paramter with * declares a paramter that can take an arbitrary number of values.

```
def fprintf(file, format, *args):
    file.write(format % args)
```

• A list can be passed as individual arguments using * notation:

```
>>> args = [3, 6]
>>> range(*args)
[3, 4, 5]
```

Doc-strings

• The first expression in a function can be a string (as in elisp).

```
def my_function():
    """Do nothing, but document it.

No, really, it doesn't do anything.
    """
    pass
```

- The first line typically contains usage information (starting with an upper-case letter, and terminated with a full stop).
- After that several more paragraphs can be added, explaining details of the usage information.
- This information can be accessed using . __doc__ or help constructs.

```
my_function.__doc__  # return doc string
help(my_function)  # print doc string
```

Anonymous Functions

• A function can be passed as an expression to another function:

```
>>> lambda x, y: x
<function <lambda> at 0xb77900d4>
```

This is a factory-pattern for a function incrementing a value:

```
def make_incrementor(n):
    return lambda x: x + n

f = make_incrementor(42)
f(0)
f(1)
```

 Functions are compared using the address of their representation in memory:

```
>>> (lambda x: x) == (lambda x: x) False
```

Exercises

- Implement Euclid's greatest common divisor algorithm as a function over 2 int parameters.
- Implement matrix multiplication as a function taking 2
 2-dimensional arrays as arguments.

More list operations

Modifiers:

- 1.extend(12) means 1[len(1):] = 12, i.e. add 12 to the end
 of the list 1.
- l.remove(x) removes the first instance of x in 1. Error, if x not in 1.

Read-only:

- ▶ 1.index(x) returns the position of x in 1. Error, if x not in 1.
- ▶ 1.count (x) returns the number of occurrences of x in 1.
- sorted(1) returns a new list, which is the sorted version of 1.
- reversed(1) returns an iterator, which lists the elements in 1 in reverse order.

Usage of lists

- Lists can be used to model a stack: append and pop().
- Lists can be used to model a queue: append und pop (0).

Higher-order functions on lists

• filter(test, sequence) returns a sequence, whose elements are those of sequence that fulfill the predicate test. E.g.

```
filter(lambda x: x % 2 == 0, range(10))
```

 map (f, sequence) applies the function f to every element of sequence and returns it as a new sequence.

```
map(lambda x: x*x*x, range(10))
map(lambda x,y: x+y, range(1,51), range(100,50,-1))
```

- reduce(f, [a1,a2,a3,...,an]) computes
 f(...f(f(a1,a2),a3),...,an)
 reduce(lambda x,y:x*y, range(1,11))
- reduce(f, [a1,a2,...,an], e) computes f(...f(f(e,a1),a2),...,an)

List comprehensions

- More readable notation for combinations of map and filter.
- Motivated by set comprehensions in mathematical notation.

```
\bullet [ e(x,y) for x in seq1 if p(x) for y in seq2 ]
 >>>  vec = [2, 4, 6]
 >>> [3*x for x in vec]
 [6, 12, 18]
 >>> [3*x for x in vec if x > 3]
 [12, 18]
 >>> [(x, x**2) for x in vec]
 [(2, 4), (4, 16), (6, 36)]
 >>> vec1 = [2, 4, 6]
 >>> vec2 = [4, 3, -9]
 >>> [x*v for x in vec1 for y in vec2]
 [8, 6, -18, 16, 12, -36, 24, 18, -54]
```

Deletion

Deletion of (parts of) a list:

```
>>> a = [-1, 1, 66.25, 333, 333, 1234.5]
>>> del a[0]
>>> a
[1, 66.25, 333, 333, 1234.5]
>>> del a[2:4]
>>> a
[1, 66.25, 1234.5]
>>> del a[:]
>>> a
[]
```

Deletion of variables:

>>> del a

Tuples

```
• >>> t = 12345, 54321, 'hello!'
 >>> t[0]
 12345
 >>> +
  (12345, 54321, 'hello!')
 >>> # Tuples may be nested:
  ... u = t, (1, 2, 3, 4, 5)
 >>> 11
  ((12345, 54321, 'hello!'), (1, 2, 3, 4, 5))
 >>> x, y, z = t
 >>>  empty = ()
 >>> singleton = 'hello',  # trailing comma
```

Sets

- set (1) generates a set, formed out of the elements in the list 1.
- list(s) generates a list, formed out of the elements in the set s.
- x in s tests for set membership
- Operations: (difference), ⊢ (union), & (intersection), ^ (xor).
- for v in siterates over the set (sorted!).

Dictionaries

- Dictionaries are finite maps, hash maps, associative arrays.
- The represent unordered sets of (key, value) pairs.
- Every key may only occur once.
- Generated using the notation:

```
{ key1 : value1, ..., keyn : valuen } or
>>> tel = dict([('guido', 4127), ('jack', 4098)])
{'jack': 4098, 'guido': 4127}
```

- Access to elements is always through the key: tel['jack'].
- Insertion and substitution is done using assignment notation:
 tel['me'] = 1234.
- Deletion: del tel['me'].
- tel.keys() returns all key values. tel.has_key('guido') returns a boolean, indicating whether the key exists.

Dictionaries

- The Python implementation uses dictionaries internally, e.g. to list all names exported by a module, or for the symbol table of the interpreter.
- Iteration over a dictionary:

```
for k, v in tel.items():
   print (k, v)
```

Named arguments:

```
def fun(arg, *args, **keyArgs): ...
```

```
fun (1, 2, 3, opt1=4, opt2=5)
```

• This binds arg = 1 and args = [2,3] and keyArgs = {opt1:4, opt2:5}.

Loop techniques

- Here are some useful patterns involving loops over dictionaries.
- Simultaneous iteration over both keys and elements of a dictionary:

```
l = ['tic', 'tac', 'toe']
for i, v in enumerate(l):
    print (i, v)
```

• Simultaneous iteration over two or more sequences:

```
for i, v in zip(range(len(l)), l):
    print (i, v)
```

• Iteration in sorted and reversed order:

```
for v in reversed(sorted(l)):
   print (v)
```

Booleans

- 0, '', [], None, etc. are interpreted as False.
- All other values are interpreted as True (also functions!).
- is checks for object identity: [] == [] is true, but [] is []
 isn't. 5 is 5 is true.
- Comparisons can be chained like this: a < b == c > d.
- The boolean operators not, and, or are short-cutting.

```
def noisy(x): print (x); return x
a = noisy(True) or noisy(False)
```

• This technique can also be used with non-Boolean values:

```
>>> '' or 'you' or 'me'
'you'
```

Comparison of sequences and other types

Sequences are compared lexicographically, and in a nested way:

```
() < (' \x00',)
('a', (5, 3), 'c') < ('a', (6,), 'a')
```

 NB: The comparison of values of different types doesn't produce an error but returns an arbitrary value!

```
>>> "1" < 2
False
>>> () < ('\x00')
False
>>> [0] < (0,)
True
```

Modules

- Every Python file is a module.
- import myMod imports module myMod.
- The system searches in the current directory and in the PYTHONPATH environment variable.
- Access to the module-identifier x is done with myMod.x (both read and write access!).
- The code in the module is evaluated, when the module is imported the first time.
- Import into the main name-space can be done by

Example

from myMod import myFun
from yourMod import yourValue as myValue

myFun(myValue) # qualification not necessary

• NB: In general it is not advisable to do from myMod import

Executing modules as scripts

- Using __name__ the name of the module can be accessed.
- The name is '__main__' for main program:

```
Example
def fib(n): ...

if __name__ == '__main__':
   import sys
   fib(int(sys.argv[1]))
```

Typical application: unittests.

Modules as values

A module is an object.

```
>>> fib = __import__('fibonacci')
>>> fib
<module 'fibonacci' from 'fibonacci.py'>
>>> fib.fib(10)
1 1 2 3 5 8
```

- fib.__name__ is the name of the module.
- fib.__dict__ contains the defined names in the module.
- dir(fib) is the same as fib.__dict__.keys().

Standard- und built-in modules

- See Python Library Reference, e.g. module sys.
- sys.ps1 and sys.ps2 contain the prompts.
- sys.path contains the module search-path.
- With import __builtin__ it's possible to obtain the list of all built-in identifiers.

```
>>> import __builtin__
>>> dir(__builtin__)
```

Packages

- A directory, that contains a (possibly empty) file __init__.py, is a package.
- Packages form a tree structure. Access is performed using the notation packet1.packet2.modul.

```
import packet.subpacket.module
print (packet.subpacket.module.__name__)

from packet.subpacket import module
print (module.__name__)
```

• If a package packet/subpacket/__init__.py contains the expression __all__ = ["module1", "module2"], then it's possible to import both modules using from packet.subpacket import *

Output formatting

- str (v) generates a "machine-readable" string representation of
- repr (v) generates a representation that is readable to the interpreter. Strings are escaped where necessary.
- s.rjust (n) fills the string, from the left hand side, with space characters to the total size of n.
- s.ljust(n) and s.center(n), analogously.
- s.zfill(n) inserts zeros to the number s in its string representation.
- '-3.14'.zfill(8) yields'%08.2f' % -3.14.
- Dictionary-Formating:

```
>>> table = {'Sjoerd': 4127, 'Jack': 4098 }
>>> print ('Jack: %(Jack)d; Sjoerd: %(Sjoerd)dfer%ort
Jack: 4098; Sjoerd: 4127
```

File I/O

- Standard-output is sys.stdout.
- f = open(filename, mode) creates a file-object f, referring to filename.
- Access modi are: 'r', 'w', 'a', 'r+' (read, write, append, read-write) plus suffix b (binary).
- f.read() returns the entire contents of the file as a string.
 f.read(n) reads the next n bytes.
- f.readline() reads the next line, terminated with '\n'. Empty string if at the end of the file.
- f.readlines() returns a list of all lines.
- Iteration over all lines:

```
for line in f: print (1)
```

Writing and moving

- f.write(s) writes the string s.
- f.seek (offset, 0) moves to position seek (counting from the start of the file).
- f.seek (offset, 1) moves to position seek (counting from the current position).
- f.seek (offset, 2) moves to position seek (counting from the end of the file).
- f.close() closes the file.

Pickling

- Arbitrary objects can be written to a file.
- This involves serialisation, or "pickling", of the data in memory.
- Module pickle provides this functionality.
- pickle.dump(x, f) turns x into a string and writes it to file f.
- x = pickle.load(f) reads x from the file f.

Saving structured data with JSON

- JSON (JavaScript Object Notation) is a popular, light-weight data exchange format.
- Many languages support this format, thus it's useful for data exchange across systems.
- It is much ligher weight than XML, and thus easier to use.
- json.dump(x, f) turns x into a string in JSON format and writes it to file f.
- x = json.load(f) reads x from the file f, assuming JSON format.
- For detail on the JSON format see: http://json.org/

JSON Example

```
Example
  tel = dict([('guido', 4127), ('jack', 4098)])
 ppTelDict(tel)
  # write dictionary to a file in JSON format
  json.dump(tel, fp=open(jfile,'w'), indent=2)
  print ("Data has been written to file ", jfile);
  # read file in JSON format and turn it into a dictic
  tel_new = json.loads(open(jfile,'r').read())
  ppTelDict(tel_new)
  # test a lookup
  the name = "Billy"
```

printNoOf(the name, tel new);

Numerical Computation using the numpy library

- numpy provides a powerful library of mathematical/scientific operations
- Specifically it provides
 - a powerful N-dimensional array object
 - sophisticated (broadcasting) functions
 - tools for integrating C/C++ and Fortran code
 - useful linear algebra, Fourier transform, and random number capabilities
- For details see: http://www.numpy.org/

Numerical Computation Example: numpy

```
Example
import numpy as np
m1 = np.array([[1,2,3],
                [7,3,4] ]); # fixed test input
\# m1 = np.zeros((4,3),int); \# initialise a matrix
r1 = np.ndim(m1); # get the number of dimensions
m, p = np.shape(m1); # no. of rows in m1 and no. of
# use range(0,4) to generate all indices
# use m1[i][j] to lookup a matrix element
print ("Matrix ml is an ", rl, "-dimensional matrix, of
```
