

F28HS Hardware-Software Interface: Systems Programming

Hans-Wolfgang Loidl

School of Mathematical and Computer Sciences,
Heriot-Watt University, Edinburgh

Semester 2 — 2022/23

⁰No proprietary software has been used in producing these slides

Outline

- 1 Lecture 1: Introduction to Systems Programming
- 2 Lecture 2: Systems Programming with the Raspberry-Pi
- 3 Lecture 3: Memory Hierarchy
 - Memory Hierarchy
 - Principles of Caches
- 4 **Lecture 4: Programming external devices**
 - Basics of device-level programming
- 5 Lecture 5: Exceptional Control Flow
- 6 Lecture 6: Computer Architecture
 - Processor Architectures Overview
 - Pipelining
- 7 Lecture 7: Code Security: Buffer Overflow Attacks
- 8 Lecture 8: Interrupt Handling
- 9 Lecture 9: Miscellaneous Topics
- 10 Lecture 10: Revision

Lecture 4. Programming external devices

Basics of the I²C interface

- So far we always used the GPIO interface to directly connect external devices.
- This is the easiest interface to use.
- It is however limited in the number of connections and devices you can connect with.
- A more general interface is the **I²C interface** or the **I²C bus**.

⁰Based on the article [The I²C-bus of the Raspberry Pi \(Der I²C-Bus des Raspberry Pi\) \(in German\), Raspberry Pi Geek 01/15](#)

Basics of the I²C interface

- I²C is a serial master-slave bus.
- It is serial, i. e. communication is one bit at a time.
- It allows to connect several masters (data-providers) with several slaves (data-consumers)
- It is designed for short-distance communication, i. e. communication on a board
- Therefore it is also used in the standard Linux kernel to monitor, e. g. temperature and other system health information
- I²C was originally developed by Philips in the 1980s, and has become an industry standard.

Technical detail on I²C

- Communication uses 2 connections:
 - ▶ a serial data line (**SDA**)
 - ▶ a serial clock line (**SCL**) for synchronising the communication
- Both connections use pull-up resistors to encode one bit (high potential = 1)
- The two sides of the communication are
 - ▶ a **master** that sends the clock information and initiates communication
 - ▶ a **slave** that receives the data
- Typical communication rates are between 100 kb/s (standard mode) and 5 Mb/s (ultra fast mode)
- **NB:** I²C was **not** designed for communicating large volumes of data

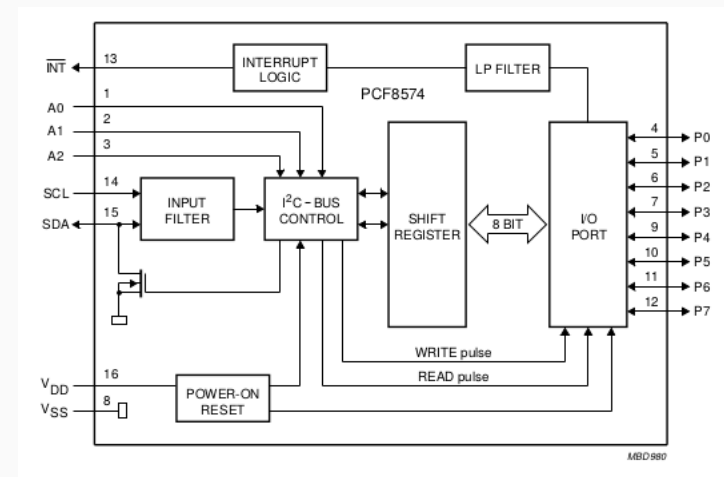

Technical detail on I²C

- I²C uses a 7-bit address space, i. e. 128 possible addresses of which 16 are reserved.
- The 8-th bit indicates the direction of the data transfer between master and slave.
- The usable address-space is defined in the technical documentation of the device. E. g.
 - PCF8574 Port-Expander 0x20 – 0x27
 - PCF8583 Clock/Calendar 0xA0 – 0xA2
- The device PCF8583 is a chip that provides an external clock, with three registers starting at 0xA0
- As an example we will now use the **PCF8574 port-expander**, which is accessed through address 0x20.
- This can be used to e. g. control an LCD display over just one data channel.

Block Diagram of the PCF8574 Port Expander

NB: 1 input data channel (**SDA**), 8 output data channels (**P0 ... P7**)

⁰From **PCF8574 Data Sheet**

What's happening on the wires?

Fig.6 Definition of start and stop conditions.

- signals start with HIGH
- a change in the SDA signal, with SCL HIGH, indicates start/stop

⁰From PCF8574 Data Sheet

How are the bits transferred?

Fig.5 Bit transfer.

- one bit is transferred during each clock pulse
- data is sampled while the SCL line is HIGH
- the SDA line needs to be stable during this HIGH period

A typical system configuration using I2C

Fig.7 System configuration.

- lines are (quasi-)bidirectional
- a device generating a message is a "transmitter"
- a device receiving is the "receiver"
- the controller of the message is the "master"
- the receivers of the message are the "slaves"

I²C on the Raspberry Pi 2

- On the RPi2 the following pins provide an I²C interface: physical Pin 03 (SDA) and Pin 05 (SCL) (these are pins 2 and 4 in the BCM numbering)
- In the following example we will use these pins to connect a PCF8574 device.
- In our configuration we connect the device with four buttons and LEDs as shown in the picture below.

Test configuration

⁰From [The I²C-bus of the Raspberry Pi \(Der I²C-Bus des Raspberry Pi\) \(in German\)](#), [Raspberry Pi Geek 01/15](#)

Software configuration

- We use the `wiringPi` library that we have installed and discussed before.
- We also need the `i2c-tools` package for the drivers communicating over the I²C bus
- To install `i2c-tools` do the following:

```
> sudo apt-get install i2c-tools
> sudo adduser pi i2c
> gpio load i2c
```
- We can now use `i2cdetect` to check the connection between our RPi2 and the external device:

```
> i2cdetect -y 1
```
- This shows that we can reach the device through address `0x20`
- The 4 high-bits in that address refer to the LEDs, the 4 low-bits refer to the buttons

Software configuration

- Initially all lines are at high, so all LEDs should light up
- To turn LEDs off, one-by-one we execute:

```
> i2cset -y 1 0x20 0x00
> i2cset -y 1 0x20 0x10
> i2cset -y 1 0x20 0x20
> i2cset -y 1 0x20 0x40
> i2cset -y 1 0x20 0x80
```

- Now we want to configure the button as an input device:

```
> i2cset -y 1 0x20 0x0f
> watch 'i2cget -y 1 0x20'
```

- Using `watch` we continuously get output about the current value issued by the button
- Pressing the button will change the observed value

A C API for I²C

- Now we want to use the I²C-bus to programmatically control external devices
- We use the following API provided by Gordon Henderson's `wiringPi` library:

```
int wiringPiI2CSetup (const int devId)
    Open the I2C device, and register the target device
int wiringPiI2CRead (int fd)
    Simple device read
int wiringPiI2CWrite (int fd, int data)
    Simple device write
int wiringPiI2CReadReg8 (int fd, int reg)
    Read an 8-bit value from a register on the device
int wiringPiI2CWriteReg8 (int fd, int reg, int value)
    Write a 8-bit value to the given register
and similar read/write interface for 16-bit values.
```

Sample Source for I²C

Using this interface we can make the LEDs blink one-by-one:

```
#include <wiringPiI2C.h>
int main(void) {
    int handle = wiringPiI2CSetup(0x20) ;
    wiringPiI2CWrite(handle, 0x10);
    delay(5000);
    wiringPiI2CWrite(handle, 0x20);
    delay(5000);
    wiringPiI2CWrite(handle, 0x40);
    delay(5000);
    wiringPiI2CWrite(handle, 0x80);
    delay(5000);
    wiringPiI2CWrite(handle, 0x00);
    return 0;
}
```

NB: We access the LEDs as a bitmask on the high 4-bits, setting the low 4-bits to zero in each case.
