Solution

Reusing HOU Augmented call-by-value reduction Reduction of unification problems

- - E - - - E - -

A ₽

Motivations

- C. Haack proposed a tool for automatic adaptation of software components that would need UMOE.
 - The approximation made was to use HOU to find unification candidates modulo β-equivalence, then check in a second time that the observational behavior are the same.
- We propose to find solutions in a single phase.
 - Possibly, finding solutions that are not needed to respect β-equivalence.

Unification Objectives Higher Order Huet's Algorithm

Unification

 Classical unification problems deals with solving equations at the syntax level modulo some equivalence relations such as associativity or commutativity.

 $b + X + Y \approx a + Z$

• Ground Solution:

$$X \mapsto a, \ Y \mapsto a, \ Z \mapsto b + a$$

Unifiers:

$$Y \mapsto a, \ Z \mapsto b + X$$

 $Y \mapsto a + T, \ Z \mapsto b + T + X$

イロト イポト イヨト イヨト

An unification problem is a set of equations $t_1 \approx t_2$ in an algebra extended with unknowns X, Y, Z..., for which equivalence is written \simeq .

(日) (周) (王) (王)

An unification problem is a set of equations $t_1 \approx t_2$ in an algebra extended with unknowns X, Y, Z..., for which equivalence is written \simeq .

Definition

An unifier for a given unification problem is a substitution θ (that replaces unknowns with terms) such for each equation $t_1 \approx t_2$ of the unification problem, $\theta t_1 \simeq \theta t_2$.

(D) (A) (A)

An unification problem is a set of equations $t_1 \approx t_2$ in an algebra extended with unknowns X, Y, Z..., for which equivalence is written \simeq .

Definition

An unifier for a given unification problem is a substitution θ (that replaces unknowns with terms) such for each equation $t_1 \approx t_2$ of the unification problem, $\theta t_1 \simeq \theta t_2$.

Definition

An unifier θ_1 is said more general than θ_2 ($\theta_1 \leq \theta_2$) iff there exists a substitution θ such that $\theta_2 = \theta \theta_1$

イロト イポト イヨト イヨト

Unification Objectives Higher Order Huet's Algorithm

In our example,

 $X \mapsto a, Y \mapsto a, Z \mapsto b + a$ $\geq Y \mapsto a, Z \mapsto b + X$ $\geq Y \mapsto a + T, Z \mapsto b + T + X$

Unification Objectives Higher Order Huet's Algorithm

In our example,

$$X \mapsto a, Y \mapsto a, Z \mapsto b + a$$

 $\geq Y \mapsto a, Z \mapsto b + X$
 $\geq Y \mapsto a + T, Z \mapsto b + T + X$

In fact there are two minimal unifiers,

$$X \mapsto a + T, \ Z \mapsto b + T + Y$$

 $Y \mapsto a + T, \ Z \mapsto b + T + X$

Objectives

- Find a most general unifier when it exists.
- Find a complete finite (finitely representable) set of minimal unifiers.
- ► Find a complete finite (finitely representable) set of unifiers.
- Enumerate a complete set of unifiers.
- Find an unifier when there is one.

The existence of an unifier is undecidable for almost every "complex" algebra, only the two last specifications can be assured. Incomplete results can also be interesting.

(D) (A) (A)

Unification Objectives Higher Order Huet's Algorithm

Higher Order

- When the algebra considered is the algebra of λ-terms modulo βη-equivalence, unification is said Higher Order Unification.
- Higher Order Unification is semi-decidable.
- ► A exhaustive "generate and test" algorithm allows to know that a specific problem has solutions.
- ► Huet's algorithms allows to restrict the search space.

(D) (A) (A)

Simply-typed λ -terms are built using the following syntax:

$$egin{array}{ccccc} I^{\sigma
ightarrow au} & ::= & \lambda x^{\sigma}. \, t^{ au} \ t^{ au} & ::= & I^{ au} ig | x^{ au} ig | X^{ au} ig | t_1^{\sigma
ightarrow au} t_2^{\sigma
ightarrow au} \end{array}$$

Definition

A unification problem is syntactically defined as:

$$P$$
 ::= P_1, P_2 | $t_1^{\scriptscriptstyle au} \approx t_2^{\scriptscriptstyle au}$ | \varnothing | \perp

(日) (周) (王) (王)

Definition

The *blocking symbol* $\neg t$ of a term *t* is defined according to the normal form of *t*, using the following matching:

$$\neg t = \cdot \iff t \downarrow_{v} = v$$

$$\neg t = x \iff t \downarrow_{v} = c[x v]$$

$$\neg t = X_{\Gamma} \iff t \downarrow_{v} = c[X_{\Gamma} v]$$

$$\neg t = \bar{X}_{\Gamma} \iff t \downarrow_{v} = c[\bar{X}_{\Gamma}]$$

 The blocking symbol plays the same role as the head variable in HOU.

・ロト ・ 同ト ・ ヨト ・ ヨト

Definition

A *bisimulation* is a congruence \sim such that:

$$t_1 \sim t_2 \Rightarrow \neg t_1 = \neg t_2$$

 $\frac{t_1 \sim t_2}{t_1 \downarrow_{\nu} \sim t_2 \downarrow_{\nu}}$ eval

Definition

The observational equivalence \simeq is the greatest bisimulation. It exists, because the union of two bisimulations is also a bisimulation.

(日) (周) (王) (王)

Calculus Semantics Observational equivalence Unification

Example

• The booleans can be distinguished.

$$\lambda x^{\gamma} . \lambda y^{\gamma} . x^{\gamma} \not\simeq \lambda x^{\gamma} . \lambda y^{\gamma} . y^{\gamma}$$

 η-equivalent terms are not necessarily observationally equivalent,

$$f^{\sigma \to \tau \to \tau'} x^{\sigma} \not\simeq \lambda z^{\tau}. f^{\sigma \to \tau \to \tau'} x^{\sigma} z^{\tau}$$

unless the term is a value.

 $\lambda z^{\tau}.\,f^{\sigma\to\tau\to\tau'}\,x^{\sigma}\,z^{\tau} \simeq \lambda z'^{\tau}.\,(\lambda z^{\tau}.\,f^{\sigma\to\tau\to\tau'}\,x^{\sigma}\,z^{\tau})\,z'^{\tau}$

Example

 Sometimes, β-equivalent terms are observationally equal in call-by-value semantics,

$$\lambda y^{lpha}.(\lambda z^{eta
ightarroweta}.y^{lpha})(\lambda x^{eta}.x^{eta}) \simeq \lambda y^{lpha}.y^{lpha}$$

Sometimes, not.

$$\lambda y^{lpha}.(\lambda z^{eta}.y^{lpha})(f^{\gamma
ightarrow eta}x^{\gamma})
ot\simeq \lambda y^{lpha}.y^{lpha}$$

Higher Order Unification Unification Modulo Observational Equivalence Solution Reusing HOU Augmented call-by-value reduction Reduction of unification problems

Solution

Towards a solving procedure...

・ロト ・四ト ・ヨト ・ヨト

Reusing HOU

The general principle of HOU can be reused: Instantiating unknowns, using the restrictions that can be grabbed using the equivalences already discovered. But,

- ► the range of normal forms in call-by-value semantics is wider than for $\beta\eta$ -reduction.
- normalization is not sufficient to know if two terms are equivalent.
- we cannot use β -reduction to deal with scope issues.

(D) (A) (A)

Augmented call-by-value reduction

Lemma Assuming $z \notin \text{fv} t_2$, $(\lambda z^{\sigma}. t_1^{\tau' \to \tau}) t^{\sigma} t_2^{\tau'} \simeq (\lambda z^{\sigma}. t_1^{\tau' \to \tau} t_2^{\tau'}) t^{\sigma}$

Lemma

Assuming $z \notin \text{fv } v$, $v^{\tau \to \tau'} \left(\left(\lambda z^{\sigma} \cdot t_1^{\tau} \right) t^{\sigma} \right) \simeq \left(\lambda z^{\sigma} \cdot v^{\tau \to \tau'} t_1^{\tau} \right) t^{\sigma}$

Lemma

 $(\lambda z^{\sigma}. z^{\sigma}) t^{\sigma} \simeq t^{\sigma}$

These are remarkable equivalences that are also β -equivalences.

イロト イポト イヨト イヨト 三日

Definition

Call-by-value augmented evaluation is defined according to:

$$\begin{split} t \downarrow_{a} &= (t \downarrow_{v}) \downarrow_{a} & \text{if t is not a normal form} \\ x \downarrow_{a} &= x \\ (\lambda z. t) \downarrow_{a} &= \lambda z. t \downarrow_{a} \\ c[x v] \downarrow_{a} &= (\lambda w. c[w] \downarrow_{a}) (x v \downarrow_{a}) \\ X_{\Gamma} \downarrow_{a} &= X_{\Pi_{a}} \\ c[\underline{X}_{\Gamma} v] \downarrow_{a} &= (\lambda w. c[w] \downarrow_{a}) (\underline{X}_{\Pi_{a}} v \downarrow_{a}) \\ c[\bar{X}_{\Gamma}] \downarrow_{a} &= (\lambda w. c[w] \downarrow_{a}) \overline{X}_{\Pi_{a}} \end{split}$$

with:

$$\begin{array}{rcl} t, \Gamma \!\!\downarrow_a &=& t \!\!\downarrow_a, \Gamma \!\!\downarrow_a \\ \varnothing \!\!\downarrow_a &=& \varnothing \end{array}$$

Others cases where unknowns do not appear are impossible:

►

$$\begin{aligned} x_1^{\tau} \approx x_2^{\tau} & \text{if } x_1^{\tau} \neq x_2^{\tau} \\ & (\lambda w^{\tau_1} \cdot m_1^{\tau}) \left(x_1^{\sigma_1 \to \tau_1} v_1^{\sigma_1} \right) \approx x_2^{\tau} \\ & (\lambda w^{\tau_1} \cdot m_1^{\tau}) \left(x_1^{\sigma_1 \to \tau_1} v_1^{\sigma_1} \right) \approx l^{\tau} \\ & (\lambda w^{\tau_1} \cdot m_1^{\tau}) \left(x_1^{\sigma_1 \to \tau_1} v_1^{\sigma_1} \right) \approx (\lambda w^{\tau_2} \cdot m_2^{\tau}) \left(x_2^{\sigma_2 \to \tau_2} v_2^{\sigma_2} \right) \\ & \text{if } x_1^{\sigma_1 \to \tau_1} \neq x_2^{\sigma_2 \to \tau_2} \end{aligned}$$

・ロト ・四ト ・ヨト ・ヨト

Some rules to guess what the unknowns should be substituted with: • if $v^{\tau} \in \Gamma$ $(\nu \underline{X}) P \rightsquigarrow P[\underline{X}_{\Gamma}^{\tau} := v^{\tau}]$ • if $z \notin \Gamma$ $(\nu \underline{X}) P \rightsquigarrow (\nu \overline{Y}) P[\underline{X}_{\Gamma}^{\sigma \to \tau} := \lambda z^{\sigma} \cdot \overline{Y}_{z^{\sigma} \Gamma}]$
