MathLang

Fairouz Kamareddine
Heriot-Watt University, Edinburgh

January 2011
**Common Mathematical Language of mathematicians: CML**

+ CML is *expressive*: it has linguistic categories like *proofs* and *theorems*.
+ CML has been refined by intensive use and is rooted in *long traditions*.
+ CML is *approved* by most mathematicians as a communication medium.
+ CML *accommodates many branches* of mathematics, and is adaptable to new ones.

  - Since CML is based on natural language, it is *informal* and *ambiguous*.
  - CML is *incomplete*: Much is left implicit, appealing to the reader's intuition.
  - CML is *poorly organised*: In a CML text, many structural aspects are omitted.
  - CML is *automation-unfriendly*: A CML text is a plain text and cannot be easily automated.
Theorem 6. [Commutative Law of Addition]

\[ x + y = y + x. \]

**Proof** Fix \( y \), and let \( M \) be the set of all \( x \) for which the assertion holds.

I) We have

\[ y + 1 = y', \]

and furthermore, by the construction in the proof of Theorem 4,

\[ 1 + y = y', \]

so that

\[ 1 + y = y + 1 \]

and 1 belongs to \( M \).

II) If \( x \) belongs to \( M \), then

\[ x + y = y + x, \]

Therefore

\[ (x + y)' = (y + x)' = y + x'. \]

By the construction in the proof of Theorem 4, we have

\[ x' + y = (x + y)', \]

hence

\[ x' + y = y + x', \]

so that \( x' \) belongs to \( M \). The assertion therefore holds for all \( x \). \( \square \)
The problem with formal logic

• No logical language is an alternative to CML
  – A logical language does not have mathematico-linguistic categories, is not universal to all mathematicians, and is not a good communication medium.
  – Logical languages make fixed choices (first versus higher order, predicative versus impredicative, constructive versus classical, types or sets, etc.). But different parts of mathematics need different choices and there is no universal agreement as to which is the best formalism.
  – A logician reformulates in logic their formalization of a mathematical-text as a formal, complete text which is structured considerably unlike the original, and is of little use to the ordinary mathematician.
  – Mathematicians do not want to use formal logic and have for centuries done mathematics without it.

• So, mathematicians kept to CML.

• We would like to find an alternative to CML which avoids some of the features of the logical languages which made them unattractive to mathematicians.
What are the options for computerization?

Computers can handle mathematical text at various levels:

- Images of pages may be stored. While useful, this is not a good representation of *language* or *knowledge*.
- Typesetting systems like LaTeX, TeXmacs, can be used.
- Document representations like OpenMath, OMDoc, MathML, can be used.
- Formal logics used by theorem provers (Coq, Isabelle, HOL, Mizar, Isar, etc.) can be used.

We are gradually developing a system named Mathlang which we hope will eventually allow building a bridge between the latter 3 levels.

This talk aims at discussing the motivations rather than the details.
The issues with typesetting systems

+ A system like LaTeX, TeXmacs, provides good defaults for visual appearance, while allowing fine control when needed.

+ LaTeX and TeXmacs support commonly needed document structures, while allowing custom structures to be created.

− Unless the mathematician is amazingly disciplined, the logical structure of symbolic formulas is not represented at all.

− The logical structure of mathematics as embedded in natural language text is not represented. Automated discovery of the semantics of natural language text is still too primitive and requires human oversight.
\begin{theorem}[Commutative Law of Addition] \label{theorem:6}

$$x+y=y+x.$$ 
\end{theorem}

\begin{proof}

Fix $y$, and $\mathfrak{M}$ be the set of all $x$ for which the assertion holds.

\begin{enumerate}
\item We have $$y+1=y',$$

and furthermore, by the construction in the proof of Theorem~\ref{theorem:4}, $$1+y=y',$$

so that $$1+y=y+1$$

and $1$ belongs to $\mathfrak{M}$.
\end{enumerate}
\end{proof}
If \( x \) belongs to \( \mathfrak{M} \), then \( x+y=y+x \),

Therefore
\[ (x+y)'=(y+x)'=y+x'. \]

By the construction in the proof of Theorem~\ref{theorem:4}, we have \( x'+y=(x+y)' \),

hence
\[ x'+y=y+x', \]

so that \( x' \) belongs to \( \mathfrak{M} \).

The assertion therefore holds for all \( x \).
Full formalization difficulties: choices

A CML-text is structured differently from a fully formalized text proving the same facts. Making the latter involves extensive knowledge and many choices:

- The choice of the underlying logical system.
- The choice of how concepts are implemented (equational reasoning, equivalences and classes, partial functions, induction, etc.).
- The choice of the formal foundation: a type theory (dependent?), a set theory (ZF? FM?), a category theory? etc.
- The choice of the proof checker: Automath, Isabelle, Coq, PVS, Mizar, HOL, ...

An issue is that one must in general commit to one set of choices.
**Full formalization difficulties: informality**

Any informal reasoning in a CML-text will cause various problems when fully formalizing it:

- A single (big) step may need to expand into a (series of) syntactic proof expressions. *Very long expressions can replace a clear CML-text.*

- The entire CML-text may need reformulation in a fully complete syntactic formalism where every detail is spelled out. New details may need to be woven throughout the entire text. The text may need to be *turned inside out.*

- Reasoning may be obscured by *proof tactics,* whose meaning is often *ad hoc* and implementation-dependent.

Regardless, ordinary mathematicians do not find the new text useful.

`Intros y H ; Elim (plus_n_Sm m y) ; Simpl rew ; Auto with arith.`

Qed.
Mathlang’s Goal: Open borders between mathematics, logic and computation

- Ordinary mathematicians *avoid* formal mathematical logic.
- Ordinary mathematicians *avoid* proof checking (via a computer).
- Ordinary mathematicians *may use* a computer for computation: there are over 1 million people who use Mathematica (including linguists, engineers, etc.).
- Mathematicians may also use other computer forms like Maple, LaTeX, etc.
- But we are not interested in only *libraries* or *computation* or *text editing*.
- We want *freedom of movement* between mathematics, logic and computation.
- At every stage, we must have *the choice* of the level of formality and the depth of computation.
Aim for Mathlang? (Kamareddine and Wells 2001, 2002)

Can we formalise a mathematical text, avoiding as much as possible the ambiguities of natural language, while still guaranteeing the following four goals?

1. The formalised text looks very much like the original mathematical text (and hence the content of the original mathematical text is respected).

2. The formalised text can be fully manipulated and searched in ways that respect its mathematical structure and meaning.

3. Steps can be made to do computation (via computer algebra systems) and proof checking (via proof checkers) on the formalised text.

4. This formalisation of text is not much harder for the ordinary mathematician than \LaTeX. Full formalization down to a foundation of mathematics is not required, although allowing and supporting this is one goal.

(No theorem prover’s language satisfies these goals.)
Mathlang captures the grammatical and reasoning aspects of mathematical structure for further computer manipulation.

A weak type system checks Mathlang documents at a grammatical level.

A Mathlang text remains close to its CML original, allowing confidence that the CML has been captured correctly.

We have been developing ways to weave natural language text into Mathlang.

Mathlang aims to eventually support all encoding uses.

The CML view of a Mathlang text should match the mathematician’s intentions.

The formal structure should be suitable for various automated uses.
What is CGa? (Maarek’s PhD thesis)

- CGa is a formal language derived from MV (N.G. de Bruijn 1987) and WTT (Kamareddine and Nederpelt 2004) which aims at expliciting the grammatical role played by the elements of a CML text.

- The structures and common concepts used in CML are captured by CGa with a finite set of grammatical/linguistic/syntactic categories: Term “$\sqrt{2}$”, set “$\mathbb{Q}$”, noun “number”, adjective “even”, statement “$a = b$”, declaration “Let $a$ be a number”, definition “An even number is..”, step “$a$ is odd, hence $a \neq 0$”, context “Assume $a$ is even”.

- Generally, each syntactic category has a corresponding weak type.
• CGa’s type system derives typing judgments to check whether the reasoning parts of a document are coherently built.

Figure 1: Example of CGa encoding of CML text
Weak Type Theory

In Weak Type Theory (or \(\text{WTT}\)) we have the following linguistic categories:

- On the \textit{atomic} level: variables, constants and binders,
- On the \textit{phrase} level: terms \(\mathcal{T}\), sets \(\mathcal{S}\), nouns \(\mathcal{N}\) and adjectives \(\mathcal{A}\),
- On the \textit{sentence} level: statements \(\mathcal{P}\) and definitions \(\mathcal{D}\),
- On the \textit{discourse} level: contexts \(\Gamma\), lines \(l\) and books \(B\).

Derivation rules

(1) \( B \) is a weakly well-typed book: \( \vdash B :: \text{book} \).

(2) \( \Gamma \) is a weakly well-typed context relative to book \( B \): \( B \vdash \Gamma :: \text{cont} \).

(3) \( t \) is a weakly well-typed term, etc., relative to book \( B \) and context \( \Gamma \):

\[
B; \Gamma \vdash t :: T, \quad B; \Gamma \vdash s :: S, \quad B; \Gamma \vdash n :: N, \\
B; \Gamma \vdash a :: A, \quad B; \Gamma \vdash p :: P, \quad B; \Gamma \vdash d :: D
\]

\( OK(B; \Gamma) \). stands for: \( \vdash B :: \text{book} \), and \( B \vdash \Gamma :: \text{cont} \)
Examples of derivation rules

- \( \text{dvar}(\emptyset) = \emptyset \) \hspace{1cm} \text{dvar}(\Gamma', x : W) = \text{dvar}(\Gamma'), x \hspace{1cm} \text{dvar}(\Gamma', P) = \text{dvar}(\Gamma') \)

\[
\begin{align*}
\text{OK}(B; \Gamma), \quad x \in V_{T/S/P}, \quad x \in \text{dvar}(\Gamma) & \quad \Rightarrow \\
B; \Gamma \vdash x :: T/S/P & \quad (\text{var})
\end{align*}
\]

\[
\begin{align*}
B; \Gamma \vdash n :: N, \quad B; \Gamma \vdash a :: A & \quad \Rightarrow \\
B; \Gamma \vdash an :: N & \quad (\text{adj-noun})
\end{align*}
\]

\[
\begin{align*}
\vdash \emptyset :: \text{book} & \quad (\text{emp-book})
\end{align*}
\]

\[
\begin{align*}
B; \Gamma \vdash p :: P & \quad \Rightarrow \\
\vdash B \circ \Gamma \triangleright p :: \text{book} & \quad (\text{book-ext})
\end{align*}
\]

\[
\begin{align*}
B; \Gamma \vdash d :: D & \quad \Rightarrow \\
\vdash B \circ \Gamma \triangleright d :: \text{book}
\end{align*}
\]
Properties of WTT

• Every variable is declared If $B; \Gamma \vdash \Phi :: W$ then $FV(\Phi) \subseteq dvar(\Gamma)$.

• Correct subcontexts If $B \vdash \Gamma :: \text{cont}$ and $\Gamma' \subseteq \Gamma$ then $B \vdash \Gamma' :: \text{cont}$.

• Correct subbooks If $\vdash B :: \text{book}$ and $B' \subseteq B$ then $\vdash B' :: \text{book}$.

• Free constants are either declared in book or in contexts If $B; \Gamma \vdash \Phi :: W$, then $FC(\Phi) \subseteq \text{prefcons}(B) \cup \text{defcons}(B)$.

• Types are unique If $B; \Gamma \vdash A :: W_1$ and $B; \Gamma \vdash A :: W_2$, then $W_1 \equiv W_2$.

• Weak type checking is decidable there is a decision procedure for the question $B; \Gamma \vdash \Phi :: W$ ?.

• Weak typability is computable there is a procedure deciding whether an answer exists for $B; \Gamma \vdash \Phi :: ?$ and if so, delivering the answer.
Definition unfolding

- Let $\vdash B :: \text{book}$ and $\Gamma \triangleright c(x_1, \ldots, x_n) := \Phi$ a line in $B$.

- We write $B \vdash c(P_1, \ldots, P_n) \stackrel{\delta}{\rightarrow} \Phi[x_i := P_i]$.

- **Church-Rosser** If $B \vdash \Phi \stackrel{\delta}{\rightarrow} \Phi_1$ and $B \vdash \Phi \stackrel{\delta}{\rightarrow} \Phi_2$ then there exists $\Phi_3$ such that $B \vdash \Phi_1 \stackrel{\delta}{\rightarrow} \Phi_3$ and $B \vdash \Phi_2 \stackrel{\delta}{\rightarrow} \Phi_3$.

- **Strong Normalisation** Let $\vdash B :: \text{book}$. For all subformulas $\Psi$ occurring in $B$, relation $\stackrel{\delta}{\rightarrow}$ is strongly normalizing (i.e., definition unfolding inside a well-typed book is a well-founded procedure).
Let $M$ be a set, $y$ and $x$ are natural numbers, if $x$ belongs to $M$ then $x + y = y + x$.
CGa Weak Type checking detects grammatical errors

Let $M$ be a set, $y$ and $x$ are natural numbers, if $x$ belongs to $M$ then $x + y$ \(\Leftarrow \text{error}\)
How complete is the CGa?

- CGa is quite advanced but remains under development according to new translations of mathematical texts. Are the current CGa categories sufficient?

- The metatheory of WTT has been established in (Kamareddine and Nederpelt 2004). That of CGa remains to be established. However, since CGa is quite similar to WTT, its metatheory might be similar to that of WTT.

- The type checker for CGa works well and gives some useful error messages. Error messages should be improved.
What is TSa? Lamar’s PhD thesis

- TSa builds the bridge between a CML text and its grammatical interpretation and adjoins to each CGa expression a string of words and/or symbols which aims to act as its CML representation.
- TSa plays the role of a user interface
- TSa can flexibly represent natural language mathematics.
- The author wraps the natural language text with boxes representing the grammatical categories (as we saw before).
- The author can also give interpretations to the parts of the text.
There is an element 0 in \( R \) such that
\[
\text{eq} \left( \text{plus} \left( a, 0 \right), a \right); \quad \}
\]
which implies
\[
\text{eq} \left( \text{plus} \left( \underline{a}, 0 \right), a \right).
\]

Therefore,
\[
0 \in R, \quad \text{eq} \left( \text{plus} \left( \underline{a}, 0 \right), a \right).
\]
Rewrite rules enable natural language representation

Take the example $0 + a0 = a0 = a(0 + 0) = a0 + a0$
Figure 2: Example for a simple shared souring
reordering/position Souring

\[ n \in \mathbb{N} \]

\[ \text{ann} = \begin{cases} \text{contains} \end{cases} \]

AMS2011
Figure 3: Example for a position souring
Let \( a \) and \( b \) be in \( \mathbb{R} \). This is expanded to

\[
T(\text{ann}) = \begin{bmatrix} <a> & <R> \\ <b> & <R> \end{bmatrix}
\]
How complete is TSa?

• TSa provides useful interface facilities but it is still under development.

• So far, only simple rewrite (souring) rules are used and they are not comprehensive. E.g., unable to cope with things like $x = \ldots = x$. 

• The TSa theory and metatheory need development.
What is DRa? Retel’s PhD thesis

- DRa Document Rhetorical structure aspect.
- **Structural components of a document** like *chapter, section, subsection,* etc.
- **Mathematical components of a document** like *theorem, corollary, definition, proof,* etc.
- **Relations** between above components.
- These enhance readability, and ease the navigation of a document.
- Also, these help to go into more formal versions of the document.
## Relations

<table>
<thead>

</tr>
</tbody>
</table>
What does the mathematician do?

- The mathematician wraps into boxes and uniquely names chunks of text.
- The mathematician assigns to each box the structural and/or mathematical rhetorical roles.
- The mathematician indicates the relations between wrapped chunks of texts.
Lemma 1. For $m, n \in \mathbb{N}$ one has: $m^2 = 2n^2 \implies m = n = 0$. Define on $\mathbb{N}$ the predicate:

$$P(m) \iff \exists n. m^2 = 2n^2 \land m > 0.$$

Claim. $P(m) \implies \exists m' < m.P(m')$. Indeed suppose $m^2 = 2n^2$ and $m > 0$. It follows that $m^2$ is even, but then $m$ must be even, as odds square to odds. So $m = 2k$ and we have

$$2n^2 = m^2 = 4k^2 \implies n^2 = 2k^2$$

Since $m > 0$, it follows that $m^2 > 0, n^2 > 0$ and $n > 0$. Therefore $P(n)$. Moreover, $m^2 = n^2 + n^2 > n^2$, so $m^2 > n^2$ and hence $m > n$. So we can take $m' = n$.

By the claim $\forall m \in \mathbb{N}. \neg P(m)$, since there are no infinite descending sequences of natural numbers.

Now suppose $m^2 = 2n^2$ with $m \neq 0$. Then $m > 0$ and hence $P(m)$. Contradiction. Therefore $m = 0$. But then also $n = 0$.

Corollary 1. $\sqrt{2} \notin \mathbb{Q}$.

Suppose $\sqrt{2} \in \mathbb{Q}$, i.e. $\sqrt{2} = p/q$ with $p \in \mathbb{Z}, q \in \mathbb{Z} - \{0\}$. Then $\sqrt{2} = m/n$ with $m = |p|, n = |q| \neq 0$. It follows that $m^2 = 2n^2$. But then $n = 0$ by the lemma. Contradiction shows that $\sqrt{2} \notin \mathbb{Q}$. 
Lemma 1.

For \( m, n \in \mathbb{N} \) one has: \( m^2 = 2n^2 \) \( \iff \) \( n = n = 0 \)

Proof.
Define on \( \mathbb{N} \) the predicate:

\[
P(m) \iff \exists n. m^2 = 2n^2 \land m > 0.
\]

Claim. \( P(m) \implies \exists n < m. P(m') \).

Indeed suppose \( m^2 = 2n^2 \) and \( m > 0 \). It follows that \( m^2 \) is even, but then \( m \) must be even, as odds squared are odd. So \( m = 2k \) and we have:

\[
2n^2 = m^2 = 4k^2 \implies n^2 = 2k^2
\]

Since \( m > 0 \), it follows that \( m^2 > 0 \), \( n^2 > 0 \), and \( n > 0 \). Therefore \( P(n) \). Moreover, \( m^2 = n^2 + n^2 > n^2 \), so \( m^2 > n^2 \), and hence \( m > n \). So we can take \( m' = n \).

By the claim \( \forall m \in \mathbb{N}. \neg P(m) \), since there are no infinite descending sequences of natural numbers.

Now suppose \( m^2 = 2n^2 \)

with \( m \neq 0 \). Then \( m > 0 \) and hence \( P(n) \). Contradiction.

Therefore \( m = 0 \). But then also \( n = 0 \).

\[ \Box \]

Corollary 1.

\( \sqrt{2} \in \mathbb{Q} \)

Proof. Suppose \( \sqrt{2} \in \mathbb{Q} \), i.e. \( \sqrt{2} = p/q \) with \( p \in \mathbb{Z}, q \in \mathbb{Z} \setminus \{0\} \). Then \( \sqrt{2} = m/n \) with \( m = |p|, n = |q| \neq 0 \). It follows that \( m^2 = 2n^2 \). But then \( n = 0 \) by the lemma. Contradiction shows that \( \sqrt{2} \notin \mathbb{Q} \). \[ \Box \]

**Lemma 1.**

For $m, n \in \mathbb{N}$ one has: $m^2 = 2n^2 \implies m = n = 0$.

**Proof.**

Define on $\mathbb{N}$ the predicate:

$$P(m) \text{ uses } \exists n. m^2 = 2n^2 \& m > 0.$$  

**Claim.** $P(m) \implies m > n.P(m')$.

Indeed suppose $m^2 = 2n^2$ and $m > 0$. It follows that $m^2$ is even, but then $m$ must be even, and hence so are $n$ and $m$. So $m = 2k$ and we have $2n^2 = m^2 = 4k^2 \implies n^2 = 2k^2$. Since $m > 0$, it follows that $m^2 > 0$, $n^2 > 0$, and $n > 0$. Therefore $P(n)$. Moreover, $m^2 = n^2 + n^2 > n^2$, so $m^2 > n^2$, and hence $m > n$. So we can take $m' = n$.

By the claim $\forall m \in \mathbb{N}. \neg P(m)$, since there are descending sequences of natural numbers.

Now suppose $m^2 = 2n^2$ with $m \neq 0$. Then $m > 0$ and hence $P(m)$. Contradiction.
The automatically generated dependency Graph

Dependency Graph (DG)
An alternative view of the DRa (Zengler’s thesis)
The Graph of Textual Order: GoTO
Zengler’s thesis

• To be able to examine the proper structure of a DRa tree we introduce the concept of textual order between two nodes in the tree.

• Using textual orders, we can transform the dependency graph into a GoTO by transforming each edge of the DG.

• So far there are two reasons why the GoTO is produced:
  1. Automatic Checking of the GoTO can reveal errors in the document (e.g. loops in the structure of the document).
  2. The GoTO is used to automatically produce a proof skeleton for a prover (we use a variety: Isabelle, Mizar, Coq).

• We automatically transform a DG into GoTO and automatically check the GoTO for errors in the document:
1. Loops in the GoTO (error)
2. Proof of an unproved node (error)
3. More than one proof for a proved node (warning)
4. Missing proof for a proved node (warning)

- To achieve this we define for each vertex $v$ of the tree:
  - $\mathcal{EN}v$ is the environment of all mathematical statements that occur before the statements of $v$ (from the root vertex).
  - Introduced symbols’:
    $$\mathcal{IN}v := \mathcal{DF}v \cup \mathcal{DC}v \cup \{s \mid s \in \mathcal{ST}v \land s \notin \mathcal{EN}v\} \cup \bigcup_{c \text{ childOf } v} \mathcal{IN}c$$
  - Used symbol:
    $$\mathcal{USE}v := \mathcal{T}v \cup \mathcal{S}v \cup \mathcal{N}v \cup \mathcal{A}v \cup \mathcal{ST}v \cup \bigcup_{c \text{ childOf } v} \mathcal{USE}c$$

- Strong textual order $\prec$: $B \prec A := \exists x(x \in \mathcal{IN}B \land x \in \mathcal{USE}A)$

- Weak textual order $\preceq$: $A \preceq B := \mathcal{IN}A \subseteq \mathcal{IN}B \land \mathcal{USE}A \subseteq \mathcal{USE}B$

- Common textual order $\leftrightarrow$: $A \leftrightarrow B := \exists x(x \in \mathcal{USE}A \land x \in \mathcal{USE}B)$
The GoTO can be generated automatically from the DG and therefore (since the DG can be produced automatically from an annotated document) automatically from an annotated document.
Graph of Textual Order for the DRa tree example
How complete is DRa?

• The dependency graph can be used to check whether the logical reasoning of the text is coherent and consistent (e.g., no loops in the reasoning).

• However, both the DRa language and its implementation need more experience driven tests on natural language texts.

• Also, the DRa aspect still needs a number of implementation improvements (the automation of the analysis of the text based on its DRa features).

• Extend TSa to also cover DRa (in addition to CGa).

• Extend DRa depending on further experience driven translations.

• Establish the soundness and completeness of DRa for mathematical texts.

DRa annotation into Mizar skeleton for Barendregt’s example (Retel’s PhD thesis)
**The generic algorithm for generating the proof skeleton**

*(SGa, Zengler’s thesis)*

A vertex is ready to be processed iff:

- it has no incoming \( \prec \) edges (in the GoTO) of unprocessed (white) vertices
- all its children are ready to be processed
- if the vertex is a proved vertex: its proof is ready to be processed

Consider the DG and GoTO of a (typical and not well structured) mathematical text:
The final order of the vertices is:

Lemma 2
Proof 2
  Definition 2
  Claim 2
  Proof C2
Lemma 1
Proof 1
  Definition 1
  Claim 1
  Proof C1

</table>
With these rules almost every axiom, definition and theorem can be translated in a way that it is immediately usable in Coq.
the left hand side of the definition is translated according to rule (coq14) with subset \( A \subseteq B \).

The right hand side is translated with the rules coq5), coq10), coq11) and coq12) and the result is

\[
\forall x \ (\text{impl} \ (\text{in} \ x \ A) \ (\text{in} \ x \ B))
\]

Putting left hand and right hand side together and taking the outer DRa annotation we get the translation

Definition subset \( A \ B := \forall x \ (\text{impl} \ (\text{in} \ x \ A) \ (\text{in} \ x \ B))\)
Figure 8: Theorem 17 of Landau’s “Grundlagen der Analysis”

The automatic translation is:

Theorem th117 x y z : (leq x y /\ leq y z) -> leq x z .
Rich skeletons for Isabelle

The corresponding translation into Isabelle is:

assumes carriernonempty: "not (set-equal R emptyset)"

**Theorem 1.6.** Commutative Law of Addition

\[
\text{eq}\text{plus} x + y = \text{plus} y + x.
\]

Figure 10: Simple theorem of the second section of Landau’s first chapter
Figure 11: The annotated theorem 16 of the Landau's first chapter
Chapter 1
Natural Numbers

1.1 Axioms

We assume the following to be given:

- A set (i.e. totality) of objects called natural numbers, possessing the properties called axioms to be listed below.

Before formulating the axioms we make some remarks about the symbols = and \( \neq \) which be used.

Unless otherwise specified, small italic letters will stand for natural numbers throughout this book.

Accordingly, the following are true on purely logical grounds:

1. For every natural number \( x \),
2. If \( x \) and \( y \) are the same number,
3. If \( x \) and \( y \) are not the same number,
4. If \( x \), \( y \), and \( z \) are the same numbers,
5. If \( x \) and \( y \) are not the same numbers.
Chapter 1 of Landau:

- 5 axioms which we annotate with the mathematical role “axiom”, and give them the names “ax11” - “ax15”.

- 6 definitions which we annotate with the mathematical role “definition”, and give them names “def11” - “def16”.

- 36 nodes with the mathematical role “theorem”, named “th11” - “th136” and with proofs “pr11” - “pr136”.

- Some proofs are partitioned into an existential part and a uniqueness part.

- Other proofs consist of different cases which we annotate as unproved nodes with the mathematical role “case”.

Figure 12: The DRa tree of sections 1 and 2 of chapter 1 of Landau’s book
• The relations are annotated in a straightforward manner.

• Each proof \emph{justifies} its corresponding theorem.

• Axiom 5 (“ax15”) is the axiom of induction. So every proof which uses induction, \emph{uses} also this axiom.

• Definition 1 (“def11”) is the definition of addition. Hence every node which uses addition also \emph{uses} this definition.

• Some theorems \emph{use} other theorems via texts like: “By Theorem ...”.

• In total we have 36 \emph{justifies} relations, 154 \emph{uses} relations, 6 caseOf, 3 existencePartOf and 3 uniquenessPartOf relations.

• The DG and GoTO are automatically generated.

• The GoTO is automatically checked and no errors result. So, we proceed to the next stage: automatically generating the SGa.
Figure 13: The DG of sections 1 and 2 of chapter 1 of Landau’s book
The GoTO of section 1 - 4
Definition geq x y := (or (gt x y) (eq x y)).
Definition leq x y := (or (lt x y) (eq x y)).

Theorem th113 x y : (impl (geq x y) (leq y x)).
Proof.
...
Qed.

Theorem th114 x y : (impl (leq x y) (geq y x)).
Proof.
...
Qed.

Theorem th115 x y z : (impl (impl (lt x y) (lt y z)) (lt x z)).
Proof.
...
Qed.
Completing the proofs in Coq

• We defined the natural numbers as an inductive set - just as Landau does in his book.

\[
\text{Inductive nats : Set :=}
| \text{I : nats}
| \text{succ : nats -> nats}
\]

• The encoding of theorem 2 of the first chapter in Coq is

\[
\text{ theorem th12 \ x : neq (succ x) x .}
\]

• Landau proves this theorem with induction. He first shows, that \(1' \neq 1\) and then that with the assumption of \(x' \neq x\) it also holds that \((x')' \neq x'\).

• We do our proof in the Landau style. We introduce the variable \(x\) and eliminate it, which yields two subgoals that we need to prove. These subgoals are exactly the induction basis and the induction step.
Proof.
intro x. elim x.

2 subgoals
x : nats
----------------------------------------------(1/2)
neq (succ I) I

-----------------------------------------------(2)
forall n : nats, neq (succ n) n -> neq (succ (succ n)) (succ n)

Landau proved the first case with the help of Axiom 3 (for all $x, x' \neq 1$).

apply ax13.

1 subgoal
x : nats
----------------------------------------------(1)
forall n : nats, neq (succ n) n -> neq (succ (succ n)) (succ n)
The next step is to introduce $n$ as natural number and to introduce the induction hypothesis:

```
intros n H.
```

1 subgoal
x : nats
n : nats
H : neq (succ n) n

-----------------------------(1/1)
neq (succ (succ n)) (succ n)

We see that this is exactly the second case of Landau’s proof. He proved this case with Theorem 1 - we do the same:

```
apply th11.
```

1 subgoal
x : nats
n : nats
H : neq (succ n) n

And of course this is exactly the induction hypotheses which we already have as an assumption and we can finish the proof:

assumption.
Proof completed.

The complete theorem and its proof in Coq finally look like this:

Theorem th12 (x:nats) : neq (succ x) x .
Proof.
intro x. elim x.
apply ax13.
intros n H.
apply th11.
assumption.
Qed.
With the help of the CGa annotations and the automatically generated rich proof skeleton, Zengler (who was not familiar with Coq) completed the Coq proofs of the whole of chapter one in a couple of hours.
Some points to consider

- We do not at all assume/prefer one type/logical theory instead of another.

- The formalisation of a language of mathematics should separate the questions:
  - which type/logical theory is necessary for which part of mathematics
  - which language should mathematics be written in.

- Mathematicians don’t usually know or work with type/logical theories.

- Mathematicians usually do mathematics (manipulations, calculations, etc), but are not interested in general in reasoning about mathematics.

- The steps used for computerising books of mathematics written in English, as we are doing, can also be followed for books written in Arabic, French, German, or any other natural language.
• MathLang aims to support non-fully-formalized mathematics practiced by the ordinary mathematician as well as work toward full formalization.

• MathLang aims to handle mathematics as expressed in natural language as well as symbolic formulas.

• MathLang aims to do some amount of type checking even for non-fully-formalized mathematics. This corresponds roughly to grammatical conditions.

• MathLang aims for a formal representation of CML texts that closely corresponds to the CML conceived by the ordinary mathematician.

• MathLang aims to support automated processing of mathematical knowledge.

• MathLang aims to be independent of any foundation of mathematics.

• MathLang allows anyone to be involved, whether a mathematician, a computer engineer, a computer scientist, a linguist, a logician, etc.
