## Overloading

### Example

```
class Vector(object):
    # constructor
    def __init__(self, coord):
        self.coord = coord
    # turns the object into string: use <> as brackets, and ; as separator
    def __str__(self):
        s = "<"
        if len(self.coord)==0:
            return s+">"
        else:
            s = s+str(self.coord[0])
            for x in self.coord[1:]:
                s = s+";"+str(x);
        return s+">"

v1 = Vector([1,2,3]); print (v1)
```

## Overloading

- Operators such as +, <= and functions such as abs, str and repr can be defined for your own types and classes.

### Example

```
class Vector(object):
    # constructor
    def __init__(self, coord):
        self.coord = coord
    # turns the object into string
    def __str__(self):
        return str(self.coord)

v1 = Vector([1,2,3])
# performs conversion to string as above
print (v1)
```

## Overloading arithmetic operations

### Example

```
import math      # sqrt
import operator # operators as functions

class Vector(object):
    ...
    def __abs__(self):
        '''Vector length (Euclidean norm).'''
        return math.sqrt(sum(x*x for x in self.coord))
    def __add__(self, other):
        '''Vector addition.'''
        return map(operator.add, self.coord, other.coord)

print(abs(v1))
print(v1 + v1)
```

## Overloading of non-symmetric operations

- Scalar multiplication for vectors can be written either `v1 * 5` or `5 * v1`.

### Example

```
class Vector(object):  
    ...  
    def __mul__(self, scalar):  
        'Multiplication with a scalar from the right.'  
        return map(lambda x: x*scalar, self.coord)  
  
    def __rmul__(self, scalar):  
        'Multiplication with a scalar from the left.'  
        return map(lambda x: scalar*x, self.coord)  
  
    • v1 * 5 calls v1.__mul__(5).  
    • 5 * v1 calls v1.__rmul__(5).
```

## Exercise (optional)

- Define a class `Matrix` and overload the operations `+` und `*` to perform addition and multiplication on matrices.
- Define further operations on matrices, such as `m.transpose()`, `str(m)`, `repr(m)`.

## Overloading of indexing

- Indexing and segment-notation can be overloaded as well:

### Example

```
class Vector(object):  
  
    def __getitem__(self, index):  
        '''Return the coordinate with number index.'''  
        return self.coord[index]  
  
    def __getslice__(self, left, right):  
        '''Return a subvector.'''  
        return Vector(self.coord[left:right])  
  
    print v1[2]  
    print v1[0:2]
```

## Types

- `type(v)` yields the type of `v`.
- Type-membership can be tested like this  
`isinstance(val, typ)`. E.g.  

```
>>> isinstance(5, float)
False
>>> isinstance(5., float)
True
```
- This check observes type-membership in the parent class. E.g.  

```
>>> isinstance(NameError(), Exception)
True
```
- `issubclass` checks the class-hierarchy.  

```
>>> issubclass(NameError, Exception)
True
>>> issubclass(int, object)
True
```

## Manual Class Generation

- `type(name, superclasses, attributes)` creates a class object with `name` name, parent classes `superclasses`, and `attributes` attributes.
- `C = type('C', (), {})` corresponds to class C: pass.
- Methods can be passed as attributes:

### Example

```
def f (self, coord):  
    self.coord = coord  
  
Vec = type('Vec', (object,), {'__init__' : f})
```

- Manual class generation is useful for **meta-programming**, i.e. programs that generate other programs.

## Controlling Attribute Access

- Access to an attribute can be completely re-defined.
- This can be achieved as follows:  
`__getattribute__(self, attr)`  
`__setattr__(self, attr, value)`  
`__delattr__(self, attr)`
- Example: Lists without append

### Example

```
class listNoAppend(list):  
    def __getattribute__(self, name):  
        if name == 'append': raise AttributeError  
        return list.__getattribute__(self, name)
```

## Properties

- *Properties* are attributes for which read, write and delete operations are defined.
- Construction:  
`property(fget=None, fset=None, fdel=None, doc=None)`

### Example

```
class Rectangle(object):  
    def __init__(self, width, height):  
        self.width = width  
        self.height = height  
    # this generates a read only property  
    area = property(  
        lambda self: self.width * self.height, # anonymous function  
        doc="Rectangle area (read only).")  
  
    print("Area of a 5x2 rectangle: ", Rectangle(5,2).area)
```

## Static Methods

- A class can define methods, that don't use the current instance (`self`).
  - ▶ Class methods can access class attributes, as usual.
  - ▶ Static methods can't do that!

### Example

```
class Static:  
    # static method  
    def __bla(): print ("Hello, world!")  
    hello = staticmethod(__bla)
```

- The static method `hello` can be called like this:  
`Static.hello()`  
`Static().hello()`

## Class/Instance Methods

- A class or instance method takes as first argument a reference to an instance of this class.

### Example

```
class Static:  
    val = 5  
    # class method  
    def sqr(c): return c.val * c.val  
    sqr = classmethod(sqr)  
  
Static.sqr()  
Static().sqr()
```

- It is common practice to overwrite the original definition of the method, in this case `sqr`.
- **Question:** What happens if we omit the line with `classmethod` above?

## Memoisation with Function Decorators

- We want a version of Fibonacci (below), that remembers previous results ("memoisation").

### Example

```
def fib(n):  
    """Compute Fibonacci number of @n@.""""  
    if n==0 or n==1:  
        return 1  
    else:  
        return fib(n-1)+fib(n-2)
```

- **NB:** This version performs an exponential number of function calls!

## Function Decoration

- The pattern

```
def f(args): ...  
f = modifier(f)
```

has the following special syntax:

```
@modifier  
def f(args): ...
```

- We can rewrite the previous example to:

### Example

```
class Static:  
    val = 5  
    # class method  
    @classmethod  
    def sqr(c): return c.val * c.val
```

- More examples of using modifiers: Memoisation, Type-checking.

## Memoisation with Function Decorators

- To visualise the function calls, we define a decorator for **tracing**:

### Example

```
def trace(f):  
    """Perform tracing on function @func@.""""  
  
    def trace_func(n):  
        print("++ computing", f.__name__, "with", str(n))  
        return f(n)  
  
    return trace_func
```

- and we attach this decorator to our `fib` function:

### Example

```
@trace  
def fib(n): ....
```

## Memoisation with Function Decorators

- Now, we implement memoisation as a decorator.
- Idea:**
  - Whenever we call `fib`, we remember input and output.
  - Before calling a `fib`, we check whether we already have an output.
  - We use a dictionary `memo_dict`, to store these values.
- This way, we never compute a Fibonacci value twice, and runtime becomes linear, rather than exponential!

## Memoisation with Function Decorators

Here is the implementation of the decorator:

### Example

```
def memoise(f):  
    """Perform memoisation on function @func@."""  
    def memo_func(n, memo_dict=dict()):  
        if n in memo_dict.keys():  
            return memo_dict[n]  
        else:  
            print("++ computing", f.__name__, "with", str(n))  
            x = f(n)  
            memo_dict[n] = x  
            print(.. keys in memo_dict: ", str(memo_dict.keys())  
        return x  
  
    return memo_func
```

## Memoisation with Function Decorators

- We attach this decorator to the `fib` function like this:

### Example

```
@memoise  
def fib(n): ...
```

- Nothing else in the code changes!
- See online sample `memofib.py`

## Interpretation

- Strings can be evaluated using the function `eval`, which evaluates string arguments as Python expressions.

```
>>> x = 5  
>>> eval ("x")  
5  
>>> f = lambda x: eval("x * x")  
>>> f(4)  
16
```

- The command `exec` executes its string argument:

```
>>> exec("print(x+1)")  
5
```

## Compilation

- This performs compilation of strings to byte-code:

```
>>> c = compile("map(lambda x:x*2,range(10))", # code
   'pseudo-file.py',          # filename for error msg
   'eval') # or 'exec' (module) or 'single' (stm)
>>> eval(c)
<map object at 0x7f2e990e3d30>
>>> for i in eval(c): print(i)
0 ...
```

- Beware of indentation in the string that you are composing!

```
>>> c2 = compile('''
... def bla(x):
...     print x*x
...     return x
... bla(5)
... ''', 'pseudo', 'exec')
>>> exec c2
25
```
