In collaboration with
Helen Waugh

Outline

- 1 Introduction to Diabetic Wound Healing
- 2 A Simple Mathematical Model
- 3 An Expanded Model
- 4 Using the Model to Understand the Treatments
- 5 Conclusions

Diabetic Wound Healing

- Wound healing in diabetics is impaired
- In some cases, wounds fail to heal over long periods (> 6 months \leftrightarrow diabetic ulcer)
- Limb amputation is required in extreme cases
- Annual cost in UK is £17M

Why is Wound Healing Impaired in Diabetics?

- There is not a clear understanding of why wound healing is impaired in diabetics

Why is Wound Healing Impaired in Diabetics?

- There is not a clear understanding of why wound healing is impaired in diabetics
- One component is that some aspects of repair fail to progress beyond the inflammatory phase

Why is Wound Healing Impaired in Diabetics?

- There is not a clear understanding of why wound healing is impaired in diabetics
- One component is that some aspects of repair fail to progress beyond the inflammatory phase
- In particular, macrophages persist for long times, with significant numbers present after a month (cf clearance after a few days in normal healing)

Why is Wound Healing Impaired in Diabetics?

- There is not a clear understanding of why wound healing is impaired in diabetics
- One component is that some aspects of repair fail to progress beyond the inflammatory phase
- In particular, macrophages persist for long times, with significant numbers present after a month (cf clearance after a few days in normal healing)
- We develop a mathematical model to investigate this persistence of macrophage numbers (and associated phenotype imbalance)

Outline

- 1 Introduction to Diabetic Wound Healing
- 2 A Simple Mathematical Model**
- 3 An Expanded Model
- 4 Using the Model to Understand the Treatments
- 5 Conclusions

Model Ingredients

- Monocytes migrate to the wound in response to $\text{TGF}\beta$ (T)
- In the wound, monocytes differentiate into one of three macrophage phenotypes, in response to micro-environmental signals:
 - Inflammatory macrophages (ϕ_I) release various cytokines that promote migration and proliferation of fibroblasts and endothelial cells
 - Repair macrophages (ϕ_R) remodel the extracellular matrix
 - Cytocidal macrophages remove bacteria and other debris (not included in the model)
- The balance between inflammatory and repair macrophages is different in normal and diabetic wounds

Model Equations

$$\begin{aligned}
 d\phi_I/dt &= \overbrace{\alpha K(T)}^{\text{influx}} + \overbrace{k_1 \phi_I (k_2 - \phi_I - \phi_R)}^{\text{proliferation}} - \overbrace{d_1 \phi_I}^{\text{removal}} \\
 d\phi_R/dt &= (1 - \alpha) K(T) + k_1 \phi_R (k_2 - \phi_I - \phi_R) - d_1 \phi_R \\
 dT/dt &= \underbrace{k_3 \phi_I}_{\text{production}} - \underbrace{d_2 T}_{\text{decay}}
 \end{aligned}$$

$$\alpha_{\text{diabetic}} > \alpha_{\text{normal}}$$

Typical Model Solution

Normal wound ($\alpha = 0.5$):

Diabetic wound ($\alpha = 0.8$):

Steady States and Model Predictions

Non-negative steady states are:

Predictions:

- The non-healing steady state appears abruptly, via a bifurcation, as α is increased
- The healed steady state persists and remains stable up to $\alpha = 1$, so that effective treatment is a possibility

Outline

- 1 Introduction to Diabetic Wound Healing
- 2 A Simple Mathematical Model
- 3 An Expanded Model**
- 4 Using the Model to Understand the Treatments
- 5 Conclusions

Key Interactions in the Expanded Model

To investigate possible therapies, we use an expanded model.

Typical Solution of the Expanded Model

Model variables: inflammatory macrophages, repair macrophages, fibroblasts, collagen, $\text{TGF}\beta$, PDGF, hyaluronan

Apligraf Treatment

Apligraf (Organogenesis, US) is an artificial skin comprising dermal and epidermal layers in a bioabsorbable scaffold.

Component	100 % Density(per cubic mm)
Neonatal Fibroblasts	1550 cells
TGF- β	0.4 pg
PDGF	1 pg
Collagen	0.45 μ g
Total Hyaluronan	18.0 μ g
Dermal Hyaluronan	15.5 μ g
Epidermal Hyaluronan	2.5 μ g

Protocol: one application per week for five weeks.

Apligraf Treatment

Apligraf (Organogenesis, US) is an artificial skin comprising dermal and epidermal layers in a bioabsorbable scaffold.

Component	100 % Density(per cubic mm)
Neonatal Fibroblasts	1550 cells
TGF- β	0.4 pg
PDGF	1 pg
Collagen	0.45 μ g
Total Hyaluronan	18.0 μ g
Dermal Hyaluronan	15.5 μ g
Epidermal Hyaluronan	2.5 μ g

Protocol: one application per week for five weeks.

A separate modelling study suggests that the epidermal layer does not play a significant role in initiating wound repair.

The Apligraf Web Site

Dermagraft Treatment

Dermagraft (Advanced Biohealing Inc, US) is an artificial dermal layer.

Component	100 % Density(per cubic mm)
Neonatal Fibroblasts	8000 cells
TGF- β	0.4 pg
PDGF	1 pg
Collagen	18.75 μg
Total Hyaluronan	80 μg
Dermal Hyaluronan	80 μg
Epidermal Hyaluronan	0 μg

Protocol: one application per week for eight weeks.

- 5 Conclusions

Separating the Treatment Components

Included: $\text{TGF}\beta$, PDGF and collagen

Excluded: hyaluronan, fibroblasts

Separating the Treatment Components

Included: fibroblasts

Excluded: $\text{TGF}\beta$, PDGF, collagen and hyaluronan

Separating Fibroblast Functions

Fibroblasts secrete a range of regulatory chemicals:

- $\text{TGF}\beta$
- PDGF
- collagen
- collagenase
- hyaluronan

Separating Fibroblast Functions

Fibroblasts secrete a range of regulatory chemicals:

- $\text{TGF}\beta$
- PDGF
- collagen
- collagenase
- hyaluronan

Question: which of these are critical to treatment success?

Separating Fibroblast Functions

Fibroblasts secrete a range of regulatory chemicals:

- $\text{TGF}\beta$
- PDGF
- collagen
- collagenase
- hyaluronan

Question: which of these are critical to treatment success?

Answer: our model predicts that only hyaluronan secretion is critical

Demonstration that Hyaluronan Production is Critical

Using the model, we simulate treatment with fibroblasts that have been modified to not produce hyaluronan, but are otherwise normal.

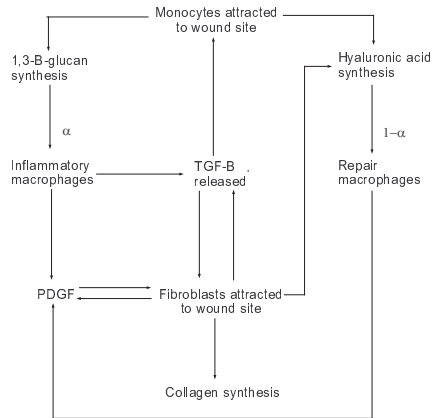

Outline

- 1 Introduction to Diabetic Wound Healing
- 2 A Simple Mathematical Model
- 3 An Expanded Model
- 4 Using the Model to Understand the Treatments
- 5 Conclusions

Conclusions

- The key component of Apligraf and Dermagraft treatments is the production of hyaluronan by the added fibroblasts
- Hyaluronan initiates healing by switching macrophages from the inflammatory to the repair phenotype

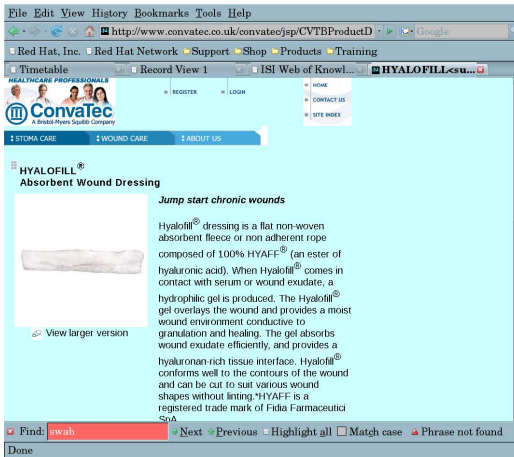

Predictions

- 1 For both therapies, the current protocols could be improved
- 2 Diabetic wound healing can be initiated simply by the addition of hyaluronan
