Vegetation Pattern Formation

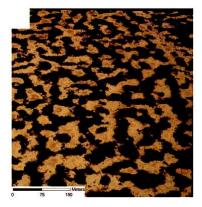

- Vegetation patterns are found in semi-arid areas of Africa, Australia and Mexico (rainfall 100-700 mm/year)
- First identified by aerial photos in 1950s
- Plants vary from grasses to shrubs and trees

Mathematical Model of Klausmeier Typical Solution of the Model

Mathematical Model of Klausmeier

Rate of change = Growth, proportional – Mortality +Random plant biomass to water uptake dispersal

$$\partial w/\partial t = A - w - wu^2 + \nu \partial w/\partial x$$

 $\partial u/\partial t = wu^2 - Bu + \partial^2 u/\partial x^2$

<ロト

Mathematical Model of Klausmeier Typical Solution of the Model

Mathematical Model of Klausmeier

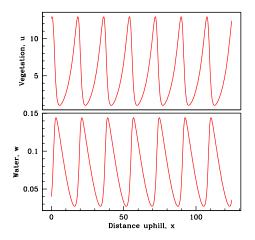

Rate of change = Growth, proportional – Mortality +Random plant biomass to water uptake dispersal

$$\partial w/\partial t = A - w - wu^2 + \nu \partial w/\partial x$$

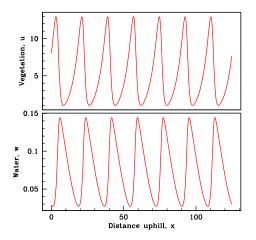

$$\partial u/\partial t = wu^2 - Bu + \partial^2 u/\partial x^2$$

The nonlinearity in wu^2 arises because the presence of roots increases water infiltration into the soil.

Conclusions

(日)

Homogeneous Steady States Approximate Conditions for Patterning An Illustration of Conditions for Patterning Predicting Pattern Wavelength

Homogeneous Steady States

 For all parameter values, there is a stable "desert" steady state u = 0, w = A.

Homogeneous Steady States Approximate Conditions for Patterning An Illustration of Conditions for Patterning Predicting Pattern Wavelength

Homogeneous Steady States

- For all parameter values, there is a stable "desert" steady state u = 0, w = A.
- When $A \ge 2B$, there are also two non-trivial steady states

$$u_u = \frac{2B}{A + \sqrt{A^2 - 4B^2}} \quad w_u = \frac{A + \sqrt{A^2 - 4B^2}}{2}$$
$$u_s = \frac{2B}{A - \sqrt{A^2 - 4B^2}} \quad w_s = \frac{A - \sqrt{A^2 - 4B^2}}{2}$$

< □ > < 同 > 三

$$u_u = \frac{2B}{A + \sqrt{A^2 - 4B^2}} \quad w_u = \frac{A + \sqrt{A^2 - 4B^2}}{2} \text{ unstable}$$
$$u_s = \frac{2B}{A - \sqrt{A^2 - 4B^2}} \quad w_s = \frac{A - \sqrt{A^2 - 4B^2}}{2} \quad \text{stable to homog}$$
pertns for $B < 2$

 Patterns develop when (u_s, w_s) is unstable to inhomogeneous perturbations

- 2

Homogeneous Steady States Approximate Conditions for Patterning An Illustration of Conditions for Patterning Predicting Pattern Wavelength

Approximate Conditions for Patterning

Look for solutions $(u, w) = (u_s, w_s) + (u_0, w_0) \exp\{ikx + \lambda t\}$

The dispersion relation $\operatorname{Re}[\lambda(k)]$ is algebraically complicated

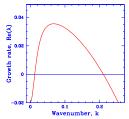

Jonathan A. Sherratt Vegetation Stripes in Semi-Arid Environments

-2

Homogeneous Steady States Approximate Conditions for Patterning An Illustration of Conditions for Patterning Predicting Pattern Wavelength

Approximate Conditions for Patterning

Look for solutions $(u, w) = (u_s, w_s) + (u_0, w_0) \exp\{ikx + \lambda t\}$

The dispersion relation $\operatorname{Re}[\lambda(k)]$ is algebraically complicated

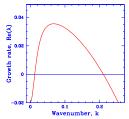

Simplification using $\nu \gg$ 1 implies that for pattern formation $A < \nu^{1/2} B^{5/4} / 8^{1/4}$

- 32

Homogeneous Steady States Approximate Conditions for Patterning An Illustration of Conditions for Patterning Predicting Pattern Wavelength

Approximate Conditions for Patterning

Look for solutions $(u, w) = (u_s, w_s) + (u_0, w_0) \exp\{ikx + \lambda t\}$

The dispersion relation $\operatorname{Re}[\lambda(k)]$ is algebraically complicated

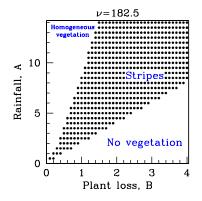

Simplification using $\nu \gg 1$ implies that for pattern formation $2B < A < \nu^{1/2} B^{5/4} / 8^{1/4}$

One can niavely assume that existence of (u_s, w_s) gives a second condition

Bifurcation Diagram for Travelling Wave ODEs

Travelling Wave Equations Bifurcation Diagram for Travelling Wave ODEs When do Patterns Form? Pattern Formation for Low Rainfall

Travelling Wave Equations

The patterns move at constant shape and speed $\Rightarrow u(x, t) = U(z), w(x, t) = W(z), z = x - ct$

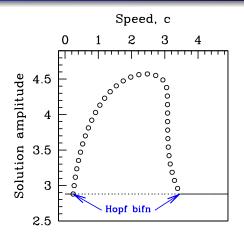

$$\frac{d^2U/dz^2 + c dU/dz + WU^2 - BU}{(\nu + c)dW/dz + A - W - WU^2} = 0$$

The patterns are periodic (limit cycle) solutions of these ODEs

Discretizing the PDEs Bifurcation Diagram for Discretized PDEs Speed vs Rainfall for Discretized PDEs Key Result Hysteresis

Discretizing the PDEs

To investigate pattern stability, we must work with the model PDEs. We discretize these in space and then use AUTO to study the resulting ODE system:

$$\partial u_i / \partial t = w_i u_i^2 - B u_i + (u_{i+1} - 2u_i + 2u_{i-1}) / \Delta x^2$$

$$\partial w_i / \partial t = A - w_i - w_i u_i^2 + \nu (w_{i+1} - w_i) / \Delta x$$

(i = 1, ..., N).

Key Result

For a wide range of rainfall levels, there are multiple stable patterns.

Discretizing the PDEs Bifurcation Diagram for Discretized PDEs Speed vs Rainfall for Discretized PDEs Key Result Hysteresis

Hysteresis

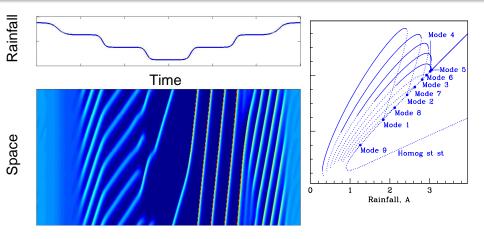

- The existence of multiple stable patterns raises the possibility of hysteresis
- We consider slow variations in the rainfall parameter *A*
- Parameters correspond to grass, and the rainfall range corresponds to 130–930 mm/year

Predictions of Pattern Wavelength Other Potential Mechanisms for Vegetation Patterns Mathematical Moral

Predictions of Pattern Wavelength Other Potential Mechanisms for Vegetation Patterns Mathematical Moral

Predictions of Pattern Wavelength

- In general, pattern wavelength depends on initial conditions
- When vegetation stripes arise from homogeneous vegetation via a decrease in rainfall, pattern wavelength will remain at its bifurcating value.

Predictions of Pattern Wavelength Other Potential Mechanisms for Vegetation Patterns Mathematical Moral

Other Potential Mechanisms for Vegetation Patterns

Rietkirk Klausmeier model with diffusion of water in the soil van de Koppel Klausmeier model with grazing

- Maron two variable model (plant density and water in the soil) with water transport based on porous media theory
- Lejeune short range activation (shading) and long range inhibition (competition for water)

All of these models predict patterns. To discriminate between them requires a detailed understanding of each model.

Predictions of Pattern Wavelength Other Potential Mechanisms for Vegetation Patterns Mathematical Moral

Mathematical Moral

Predictions based only on linear stability analysis are misleading for this model

Predictions of Pattern Wavelength Other Potential Mechanisms for Vegetation Patterns Mathematical Moral

Pattern Selection

- For a range of rainfall levels, there is more than one stable pattern. Which will be selected?
- We consider initial conditions that are small perturbations of the coexistence steady state (u_s, v_s).
- All such initial conditions give a pattern, but the wavelength depends on the initial perturbation

- We consider initial conditions that are small perturbations of the coexistence steady state (u_s, v_s).
- All such initial conditions give a pattern, but the wavelength depends on the initial perturbation

The wavelength is close to that predicted by linear stability analysis

Predictions of Pattern Wavelength Other Potential Mechanisms for Vegetation Patterns Mathematical Moral

Pattern Selection on Larger Domains

The proximity of the wavelength to the most linearly unstable mode continues as the domain is enlarged

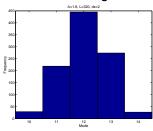

Predictions of Pattern Wavelength Other Potential Mechanisms for Vegetation Patterns Mathematical Moral

Pattern Selection on Larger Domains

The proximity of the wavelength to the most linearly unstable mode continues as the domain is enlarged

But it does not apply for other initial conditions, such as perturbations about (u_u, w_u)
