The Complex Ginzburg-Landau Equation

I consider a generic oscillator model, the complex Ginzburg-Landau equation:

$$A_t = (1 + \mathrm{i}b)A_{xx} + A - (1 + \mathrm{i}c)|A|^2A.$$

I will look exclusively at b = 0. Then writing

$$A(x,t) = e^{-iat}[u(x,t) + iv(x,t)]$$

gives a reaction-diffusion system of " λ – ω " type:

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + (1 - r^2)u - (a + cr^2)v$$

$$\frac{\partial v}{\partial t} = \frac{\partial^2 v}{\partial x^2} + (a + cr^2)u + (1 - r^2)v$$
where $r = \sqrt{u^2 + v^2}$

Applications of Wavetrains Transition from Pattern to Disorder The Complex Ginzburg-Landau Equation Amplitude and Phase Equations Wavetrain Generation by Dirichlet Bndy Conditions

A D > A P >

Amplitude and Phase Equations

To study these equations, it is helpful to use the variables $r(x, t) = \sqrt{u^2 + v^2}$ and $\theta(x, t) = \tan^{-1}(v/u)$, giving

$$r_t = r_{xx} - r\theta_x^2 + r(1 - r^2)$$

$$\theta_t = \theta_{xx} + \frac{2r_x\theta_x}{r} + a - cr^2$$

There is a family of wavetrain solutions ($0 < r^* < 1$):

$$\begin{cases} r = r^* \\ \theta = \left[(a + cr^{*2})t \pm \sqrt{(1 - r^{*2})}x \right] \end{cases}$$

$$\leftrightarrow \begin{cases} u = r^* \cos\left[(a + cr^{*2})t \pm \sqrt{(1 - r^{*2})}x \right] \\ v = r^* \sin\left[(a + cr^{*2})t \pm \sqrt{(1 - r^{*2})}x \right] \end{cases}$$

Applications of Wavetrains Transition from Pattern to Disorder The Complex Ginzburg-Landau Equation Amplitude and Phase Equations Wavetrain Generation by Dirichlet Bndy Conditions

Wavetrain Generation by Dirichlet Bndy Conditions

I consider these equations subject to u = v = 0 at x = 0

Applications of Wavetrains Transition from Pattern to Disorder The Complex Ginzburg-Landau Equation Amplitude and Phase Equations Wavetrain Generation by Dirichlet Bndy Conditions

Wavetrain Generation by Dirichlet Bndy Conditions

I consider these equations subject to u = v = 0 at x = 0

Dirichlet boundary conditions are very natural in ecology, at transitions between different types of habitat.

I consider these equations subject to u = v = 0 at x = 0

Applications of Wavetrains Transition from Pattern to Disorder The Complex Ginzburg-Landau Equation Amplitude and Phase Equations Wavetrain Generation by Dirichlet Bndy Conditions

Wavetrain Generation by Dirichlet Bndy Conditions

Conclusion

Dirichlet boundary conditions generate a wavetrain

$$r = R^* \tanh\left(x/\sqrt{2}\right)$$

$$\theta_x = \Psi^* \tanh\left(x/\sqrt{2}\right)$$

$$R^* = \left\{\frac{1}{2}\left[1+\sqrt{1+\frac{8}{9}c^2}\right]\right\}^{-1/2}$$

$$\Psi^* = -\operatorname{sign}(c)\left(1-R^{*2}\right)^{1/2}$$

Applications of Wavetrains Transition from Pattern to Disorder The Complex Ginzburg-Landau Equation Amplitude and Phase Equations Wavetrain Generation by Dirichlet Bndy Conditions

Wavetrain Generation by Dirichlet Bndy Conditions

Conclusion

Dirichlet boundary conditions generate a wavetrain

$$r = R^* \tanh\left(x/\sqrt{2}\right)$$

$$\theta_x = \Psi^* \tanh\left(x/\sqrt{2}\right)$$

$$R^* = \left\{\frac{1}{2}\left[1+\sqrt{1+\frac{8}{9}c^2}\right]\right\}^{-1/2}$$

$$\Psi^* = -\operatorname{sign}(c)\left(1-R^{*2}\right)^{1/2}$$

The wavetrain of amplitude R^* is stable $\Leftrightarrow |c| < 1.110468...$

What happens when |c| > 1.110468...?

Sources, Sinks, and Convective Instability

Question: How can an unstable wavetrain persist between the sources and sinks?

Answer: Any growing perturbations moves, and is absorbed when it reaches a sink.

Jonathan A. Sherratt

Sources, Sinks, and Convective Instability Literature on Sources and Sinks Numerical Study of Source-Sink Separations

Previous Mathematical Work on Sources and Sinks

- Sources are "Nozaki–Bekki" holes (Nozaki & Bekki, Phys. Lett. A 110: 133-135, 1985), on which the literature is extensive (> 100 citations).
- Sinks are also well studied, though only numerically.
- Important work on classification of "defects" has been done by Sandstede & Scheel (SIAM J. Appl. Dyn. Syst. 3: 1-68, 2004).
- But patterns of sources and sinks have received almost no attention.

Question: are there constraints on the distances separating sources and sinks?

Sources, Sinks, and Convective Instability Literature on Sources and Sinks Numerical Study of Source-Sink Separations

Conclusions on Source-Sink Separations

Numerical results suggest: source-sink separations appear to be constrained to a discrete set of possible values.

Analytical study shows:

arg [exp
$$(-L_{-}(1 + i\delta)/\sqrt{2})$$

+ exp $(-L_{+}(1 + i\delta)/\sqrt{2})$]
= constant

to leading order for large L_- , L_+ where

$$\delta^2 = 11 - 24 \left/ \left(\left[1 + \sqrt{1 + \frac{8}{9}c^2} \right] \right) \right)$$

- 4 The Patterned Transition From Periodicity to Chaos

5 Conclusions

Summary and Conclusions Publications

Summary and Conclusions

- Wavetrain patterns are a generic feature of oscillatory systems
- The transition from wavetrain patterns to chaos occurs via patterns of sources and sinks
- There is a discrete family of possible source-sink separations
- There is a clear, structured transition in the source-sink pattern, leading to chaos
- The chaos is initially localised, and gradually becomes global
